At the meeting of the Royal Academy of Medicine in Ireland, May 17, 1889, Dr. J. H. Nicholas read a paper on abdominal section in typhoid fever. The histories of two cases were read and specimens shown for the purpose of inquiring whether or not opening the abdomen is justifiable in perforation of the intestine in typhoid fever. It was assumed that the existence of diffused acute peritonitis might be accepted as a diagnosis of perforation existing; and as recovery, with fecal matter exuded into the cavity of the abdomen was absolutely impossible, it was suggested that before collapse appeared the abdomen might be opened and washed out, and the opening sewed to the anterior wall. Among the many objections, the following were mentioned: difficulty of diagnosis; condition of the patient; difficulty of finding the perforation; diseased condition of the wall of the gut; many cases diagnosticated as perforation having recovered. The author endeavored to answer these objections.

Dr. Ball said the treatment of perforating ulcers from typhoid fever by abdominal section had been adopted on several occasions with results uniformly fatal; that such a result was to be expected was due to the fact that the union of intestinal wounds demanded not only a very accurate adjustment but a very rapid healing of the parts.—*British Medical Journal*, June 15, 1889.

Recovery from a Snake Bite.

An interesting case of recovery from the bite of a snake is recorded in a foreign medical contemporary. A medical man, Dr. Zeperino Meirelles, was called to a robust planter, 55 years old, who had just been bitten by a poisonous snake in the neighborhood of the left external malleolus. A ligature was at once tightly applied round the limb above the wound. About two

hours afterwards there was injected into the four openings made in the skin by the teeth of the animal a hundred grammes of distilled water containing one gramme of permanganate of potash. At the same time the wounds were dressed with lint soaked in a solution of the same strength. Seven hours after the bite the toxic symptoms commenced. The patient became greatly agitated, severe pains were felt in the abdomen, blood-stained expectoration was frequent, and the urine was also blood-stained. The conjunctive, the buceal, and pharyngeal mucous membranes were greatly injected, the gums tender and bleeding on pressure, and blood-stained serum oozed from the wounds. Respiration was difficult, the pulse accelerated, and noises in the ears were much complained of. About an hour and a half after two further injections had been given the condition of the patient became complicated with vertigo, hallucinations and vomiting. A fourth injection was followed by great feebleness and loss of sight. Without being discouraged, Dr. Meirelles administered three more injections. The last was effectual, and the patient fell into a troubled sleep. He was convalescent at the end of a week.—*Medical Press*, July 10, 1889.

Melon-Seed Bodies in Joints and Tendon-Sheaths.

Considerable light has recently been thrown by Schuchardt on the mode of production of these bodies (*Centralblatt für Chirurgie*, April 27, 1889). After criticising the generally accepted views of their formation by fibrinous deposition, he gives at some length the results of his own microscopical examination of specimens that have come under his notice. His researches seem to show that the mode of their origin is essentially different from that which has been just referred to. They either consist of altered portions of the lining membrane of the walls of the cavity itself in which they are contained, or they are developed in connection with the tendon-sheaths; whilst a careful examination of them shows that coagulated fibrin does not really enter into their composition. In more than one instance the living membrane of the joint was found to be covered with a viscid substance more or less laminated in character, and here and there already causing adhesions to take place between the opposing surfaces of the joints. These glutinous masses appear to be composed of partially "necrosed" portions of the joint wall, which instead of passing away, remain connected with the wall and likewise become attached to one another. The movements of the surfaces of the joints upon each other then cause these bodies to drop into the joints, where they lie loose as melon-seed bodies; and if the joint is in a fairly healthy condition, they may be evacuated and leave behind a good and useful joint.—*Practitioner*, June, 1889.

Ovariotomy During Pregnancy.

In the *Gaceta Médica*, Aug. 15, 1889, Dr. T. Noriega, of the City of Mexico, gives an interesting account of a case in which he did a successful ovariotomy upon a pregnant woman. The patient was twenty-four years old and in the fifth month of pregnancy.

The account is very complete and accurate and is illustrated with a beautiful wood-cut.

Sulphur as a Disinfectant.

In disinfection by burning sulphur, Dr. Squibb recommends the evaporation of an amount of water equal to four times the amount of sulphur burnt. To render the disinfection effective, it is necessary that sufficient moisture be present in the atmosphere with which the sulphurous oxide may unite. The water may be evaporated in a shallow dish, heated to boiling. The sulphur, placed in a smaller dish set in the water bath, is moistened with alcohol and ignited. Walls covered with kalsomine or whitewash should be dampened with a brush before the sulphur is burnt.

Treatment of Catarrh of the Bladder.

Dr. L. Frey, of Vienna, strongly recommends the treatment of chronic catarrh of the bladder with thorough irrigation with warm water, followed by injection of a pint of lukewarm water to which has been added a tablespoonful of the following mixture:

℞	Iodoform	5 ounces
	Glycerine	4 fl. ounces
	Distilled water	1 fl. ounce
	Gum tragacanth	12 grains

—*Wiener med. Presse*, May 19, 1889.

NEWS.

—Dr. A. J. Louder has removed from White Haven, Pa., to Pioche, Nevada.

—Dr. Mary B. Winslow has removed from Seattle, W. T., to Port Townsend, W. T.

—Surgeon General Hamilton, of the Marine Hospital Service, has been authorized by the President to keep open the quarantine stations at Delaware Breakwater, Tortugas Keys, Sapelo Sound, and Cape Charles.

—Dr. Benjamin Lee, Secretary of the Pennsylvania State Board of Health, returned from Johnstown Sept. 28, and reported the discontinuance of work by the Board together with the fact that the town is in good hygienic condition.

—Dr. Sternberg, of the U. S. Army, accompanies the excursionists of the Congress of American Nations, in the capacity of surgeon. He was selected by the Secretary of War for this duty because of his familiarity with the Spanish language and the Spanish-American people.

—An epidemic of malignant diphtheria has broken out in Carbondale, Pa., and about seventy-five cases had been reported by Oct. 3. In many cases entire families are stricken down. Eight years ago an epidemic of the same disease visited Carbondale and did fearful damage.

—It is reported from Portsmouth, N. H., that Dr. H. F. Bradbury, who has figured conspicuously in connection with the bogus medical colleges in Vermont, New Hampshire, and Massachusetts, referred to in the REPORTER, Oct. 5, was arrested in Norway, Maine, Oct. 3, and brought to Portsmouth, where he was arraigned before the United States Commissioner, charged with fraudulent use of the mails. The Commissioner held him in $10,000 for the Circuit Court at Concord, October 8.

—At the regular monthly meeting of the Norristown Hospital Trustees in Philadelphia the physician's report showed a population of 892 males and 858 females. The system of inspectorship which was adopted by the Board some time ago, for the purpose of preventing, as far as possible, cruelty to patients, was explained. Alcoves have been built in which inspectors will be placed. From these lookouts the doings of the attendants all over the wards can easily be seen, and any dereliction of duty will be promptly reported. The system is ready for practical operation.

HUMOR.

DASHER—"I hope you don't object to my smoking?"

Rev. Mr. Mylde—"N—not in the least, if—you don't object to my being sick."—*Pick Me Up.*

TWINS. — Mrs. O'Finnegan — "This, mum, is me twin bye, Mickey." Mrs. Worthington—"Indeed; where is the other one?" Mrs. O'Finnegan—"Shure, he's over to his mother's house, Mrs. Toule's. Her Jimmy and me Mickey was twins—born on the same day, mum."

ENOUGH TO KILL HIM.—Family Physician (greatly shocked) — "Jehones, you should have sent for me sooner; how long have you been in this fearful condition?" Jehones (with a hollow cough)—"About two months; ever since the beginning of December, in fact." Family Physician—"You are still employed on the staff of the *Morning Tomahawk*, are you not?" Jehones—"Yes." Family Physician—"You must have been working too hard." Jehones (feebly)—"I am afraid I have; I spend two or three hours every day trying to compile a department of 'Bright Things' from the *Congressional Record*."—*Chicago Tribune.*

PEDAGOGICAL. — Two eccentric-looking women, whose description seemed to identify them as Mrs. Malaprop and Mrs. Partington, were in a Fourth avenue car yesterday, and entertained the passengers with their brilliant remarks. "I see from the papers," said one of them, "that they have fixed up a college of pedagogy and are going to give degrees. I think it is a horrid outrage. I won't say nothing about those Madison Square affairs, which certainly have a bad influence on the people. The idea! to watch a lot of crippled fools running around a ring for a whole week! I won't say nothing about that, but when they start a reg'lar college to train more such fools I think the law, or Mayor Grant, or Congress, or somebody ought to stop it." "Why, Mrs. Partington," exclaimed her companion, with a superior smile, "you've made a dreadful mistake. That College of Pedagogy and the training school are not for walkers at all. It doesn't mean that." "Of course it does; if it doesn't, what does it, then?" remarked the first, with charming consistency. "Corn doctors, of course," was the answer, and at the same moment the car ran off the track.—*New York Tribune.*

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe, and healthful Home.

Resident Medical Officers:

Clinical Lecture.

THE USE OF CREOLIN. TREATMENT OF OCCIPITO-POSTERIOR POSITIONS.[1]

BY EDWARD P. DAVIS, M. D.,

VISITING OBSTETRICIAN TO THE PHILADELPHIA HOSPITAL, ETC.

Gentlemen: This morning I wish to call your attention for a portion of my hour to a new antiseptic agent which has been attracting the notice of the profession of late in Germany, and more recently in this country, and which we have introduced with satisfactory results into general use in the Maternity Wards of this Hospital. I refer to creolin.

This germicide is a proprietary product of the same order as carbolic acid. It is obtained by a dry distillation of the best varieties of coal, and is an oily liquid of a strong tarry odor and a dark brown or black color. In the unadulterated form it leaves a stain upon the hands when immersed in it. It is soluble in alcohol, ether and chloroform, but insoluble in water. When mixed with the latter, however, it forms a uniform emulsion, slightly alkaline in reaction, and this, through a series of bacteriological tests, has been proven to be possessed of strong antiseptic properties.

As you know, the employment of the antiseptic agents now in general use, namely, the bichloride of mercury and carbolic acid, is attended with several marked disadvantages. Quite a number of cases of severe and even fatal poisoning have been reported in medical literature from the use of both of these germicides as vaginal douches and for intra-uterine injections, while carbolic acid in improper dilution has repeatedly produced severe burns of the unfortunate patient. Such being the case, any germicide which possesses the antisep-

[1] Delivered at the Philadelphia Hospital.

tic properties of these agents, and at the same time is free from their deleterious effects must of necessity commend itself to the profession, and rapidly grow into favor. Such a germicide we believe creolin to be. The observations of all of the investigators who have tested it in series of cases are unanimous in the assertion that it is a comparatively harmless product unattended with marked poisonous properties, and that when injected into the genital canal of the parturient woman it acts as a lubricant superior to vaseline or carbolized oil. It has also been found to be of considerable value as an hæmostatic.

The method of using creolin in labor is as follows: To increase its lubricant and cleansing properties, and in order that it may more thoroughly permeate the entire vaginal canal, the Germans have been in the habit of adding mollin, a fatty soap made at present exclusively in Germany, to make a two per cent. emulsion of the creolin. But as mollin is expensive in this country, and as we have found green soap to be equally valuable when so used, we have substituted it in the place of the other. The following is the formula of the emulsion as used in our wards:

℞ Creolin . . . . . f℥i
Saponis viridis . . . . . ℥ii
Aquæ . . . . . f℥iii
Liq. Potassæ . . . . . f℥iii
M.

I will pass around these two bottles containing some of the preparation that you may observe its appearance and odor.

A bottle of this material is kept in the ward, and all that is necessary in order to make a two per cent. emulsion for immediate use, is to mix fifteen drachms in a pint of warm water: we then employ it as a vaginal douche before labor, injecting the emulsion by a glass syringe, fully distending the vagina before the fluid escapes. After labor we are accustomed to employ a two per cent. emulsion of creolin with water only as a vaginal douche, and if needed, as an intra-uterine injection. Such douches are given morning and night in all cases where stitches have been inserted, and, as I have said before, with excellent results. The bichloride of mercury is still used for disinfecting the hands and external parts of the patient.

While on the subject of the antiseptic treatment of labor, I wish to show you the form of antiseptic pad which we use now in the Maternity Wards of this Hospital. In place of the napkins which were formerly used, and which were made to render service in a large number of cases, by thorough cleansing in the laundry, we employ now pads made of oakum covered with a little ordinary cotton batting (not absorbent cotton), the whole being enclosed in a piece of common cheese-cloth. These are soaked in a solution of bichloride, 1 to 2,000, and then dried ready for use. They should be removed when soiled, and burned, in this way avoiding a second using. It has been found that on an average six of these will be required on the first day, and after that four a day. The cost is but $1.90 per one hundred and fifty pads, or one and one-quarter cents per pad, so you will see that the expense is reduced to the minimum.

I will now give you the history of a case of occipito-posterior position which was recently delivered in our Wards, and which is especially interesting and instructive.

M. O'B., æt. 32. Primipara. The patient's mental condition was such that an accurate history of her condition prior to admission could not be obtained. She said that her limbs were at one time greatly œdematous, but an examination of her urine was negative in its results, no albumin or casts being present. Labor pains began at twelve o'clock midnight of Saturday, September 14. At six in the morning of the fifteenth she was sent to the Maternity Wards. The os then barely admitted the examining finger, and the labor pains may be said to have scarcely begun. During the whole of Sunday she complained of pain, but no progress was made. That night to lessen her pain one grain of the extract of opium was administered by the rectum, pains continued all night and the next day, and by six o'clock Monday evening the os had reached the size of a dollar, and dilatation was progressing. By eleven o'clock dilatation was complete. The diagnosis of the position was now made, confirming that obtained by an external examination and auscultation, namely, right occipito-posterior. About two o'clock in the morning of Tuesday, the occiput seemed to lie almost directly toward the sacrum. At three-thirty o'clock the head was on the perineum in the right occipito-posterior position, and remained so for two hours, save that a partial rotation occurred, the head afterwards falling back, however. The uterus now became tonically contracted,

and the contraction ring could be felt plainly through the abdominal walls; fœtal heart sounds became rapid and weak. At seven-thirty o'clock, after the patient had been catheterized, and a creolin douche had been given, ether was administered and Simpson's forceps were applied to the head in the pelvic axis and traction made. After a few moments' firm traction the head advanced. The uterus now seemed to be relieved of some of its spastic condition, and during the last traction contracted strongly, delivering the head. The vagino-rectal septum was lacerated through a length of from one and a half to two inches. As soon as the placenta had been expressed, stitches were inserted as follows: A continuous catgut suture was first applied to the rectal side from the apex of the tear downward; then several silk sutures were applied deeply in the vaginal side, and lastly the perineum was closed with deep silk sutures. The vagina and rectum were then washed out with a two per cent. creolin emulsion, and a pad placed between the knees, which were bound together until the ether narcosis had passed off. The patient was placed upon a liquid diet, and her urine drawn by the catheter every eight hours. Recovery from the etherization was prompt. The patient's condition is now very fair. The uterus is firmly contracted, but the external surface seems to bear two small fibroid tumors, which, indeed, had been felt before labor had commenced. Her temperature after labor was $100^{2°}$, pulse 136, respiration 28. The temperature began to fall at once, and by evening of the next day was almost normal. The lochia have been normal in appearance and amount.

The child, which presented the characteristic appearance of a child delivered in occipito-posterior position—and, gentlemen, permit me to say there is no more sorry appearance presented, than by a child so delivered—breathed feebly immediately on delivery, but after receiving a hot bath, its respirations became stronger, and it has done well since. It was covered with meconium when born, a sign that it had undergone dangerous pressure during birth. It is now somewhat jaundiced, and has presented a most obstinate case of constipation, having had but one spontaneous evacuation of the bowels since delivery.

In closing my lecture this morning I will do so by giving to you some statistics of 400 cases of occipito-posterior position, published recently by a French writer (Bataillard, in *Annales de Gynécologie et d'Obstetrique*). He believes that clinical observations of occipito-posterior positions show that most of these cases terminate as occipito-anterior, namely 353 out of 400; that when the fetus weighs five or six pounds, in primiparæ the labors are two hours longer in the occipito-posterior position than in the occipito-anterior, and that when it weighs from six to seven pounds, labor is three and one-half hours longer in the posterior than in the anterior position. In multiparæ the duration of labor is about the same, but when the child weighs about seven pounds there is very little difference between the duration of the labor in the two positions. Out of the five hundred cases of occipito-posterior positions, there were but two maternal deaths, one from eclampsia and one from sepsis, making the maternal mortality in occipito-posterior cases .5 per cent., while in 660 cases of occipito-anterior cases the mortality was .46 per cent. The fetal mortality in the occipito-anterior cases was .76 per cent., while in the occipito-posterior cases it was 2 per cent. It is very evident, therefore, that our greatest anxiety in these cases should be regarding the life of the child. If closed at once under antiseptic precautions lacerations of the perineum in these cases generally heal, and do not seriously complicate the mother's recovery.

—To Handle Small Thin Sections: A very convenient trowel for this purpose is made by inserting the head of a large needle in a penholder or other suitable handle; then filing the needle flat on two opposite sides, and breaking off the point. Such an instrument does not take up as much fluid with a small specimen as the ordinary trowel does. It also has other advantages over the customary methods of handling small thin sections of either animal or vegetable tissue.

—Cover Glasses, as sold nowadays, are not quite clean. They should be washed in distilled water and kept in a wide-mouthed bottle filled with alcohol acidulated with hydrochloric acid. They are readily cleaned with tissue or Japanese napkin paper between the thumb and forefinger. The patent devices for cleaning cover glasses are only serviceable to make a show of those who use them.

COMMUNICATIONS.

REMARKS ON A CASE OF OVARIOTOMY.

BY R. STANSBURY SUTTON, M. D.,
SURGEON TO TERRACE BANK HOSPITAL FOR WOMEN. ALLEGHENY, PA.

The case you have just seen operated upon was a specimen of those not infrequently met with, viz. : a large multilocular cyst, with a twisted pedicle and extensive adhesions. The patient's temperature has been above normal every day for probably three months; she has had repeated sweats and considerable pain of a colicky character. During the last twelve years, I have met with and operated on a number of cases like this one. The twisting of the pedicle, followed by adhesions of the sac to the surrounding viscera and abdominal wall, has not, in my experience, save in a solitary instance, added to the mortality.

In 1877 I saw a woman ten days after her confinement and diagnosticated the presence of an ovarian cyst with a twisted pedicle, and urged an immediate operation. She was the daughter of a doctor, who had no faith in the diagnosis, and absolutely no knowledge of abdominal surgery, and was far advanced in years. She was permitted to go on unoperated upon for ten days longer, during the last four or five of which she had a temperature of 104° and severe sweats, and showed great exhaustion. When it was evident that she would die, I was requested to operate upon her, and did so. The pedicle was twisted, the cyst was gangrenous, and filled with bloody fluid, and there were numerous recent and soft adhesions. In this way nature tried to save her, but failed. There was one peculiarity about this operation which I will venture to mention. It was this: after taking the cyst out of the abdomen and dropping the ligated pedicle, I poured in to the cavity of her abdomen several tin cups full of hot water, and sponged it out again before closing the wound. After the woman died, which she did within three or four days, I imagined that the washing out of her abdominal cavity with hot water might have had something to do with her death. Now, when it is the rule to wash out the abdominal cavity after abdominal section, we see how difficult a thing it is to always determine, in a new procedure, whether we are right or wrong.

You will observe that to-day we gave chloroform. I was brought up immensely prejudiced in favor of ether, but its tendency to congest unhealthy kidneys, to irritate sensitive bronchial surfaces, to produce nausea and vomiting and thereby favor the formation of secondary stitch-hole abcesses, has shaken my faith in its applicability in abdominal surgery. My assistant, Dr. Williamson, who was educated in the University of Berlin, has as great an antipathy to ether as I used to have to chloroform, consequently we have about ceased to use ether, using chloroform instead. Before operation this woman was given a bath, and her bowels were cleared out by means of a purgative given thirty-six hours before the time of the operation. For twenty-four hours before the operation she was fed on Bovinine and Beef Peptonoids; beyond this she had no preparatory treatment. Occasionally I quininize patients prior to operation.

You observe that no medicated liquids have been used during the operation; that the sponge water, and that used over the instruments, as well as the water in the irrigating reservoir, was simple clean, well-boiled water. You probably observed that I used sponges very little. This tube on the end of the hose washes out the abdominal cavity rapidly and effectually, leaving nothing to be removed by the sponge excepting a little water.

All raw points, you will remember, were touched with the Paquélin cautery. A drainage-tube was not put in, as there was no necessity for it, and the wound was closed with silkworm gut sutures, three or four to the inch. You will also observe that I have operated with but one assistant, my head nurse giving the anæsthetic, and two nurses waiting upon me. The nurse giving the anæsthetic has been at my side during operations for six years, and she and I have done an ovariotomy alone. I dislike a multiplicity of assistants; students of medicine are never admitted to my operations, and rarely more than two or three physicians. It is more than two and a half years since I have had a death from ovariotomy or oöphorectomy, and in my last forty-four ovariotomies and oöphorectomies the temperature has not, during the first week after operation, risen above 101° and in many of them did not reach 100°.

This is my argument to-day for disclaim-

ing all faith in the introduction of solutions of carbolic acid and bichloride of mercury into abdominal surgery. I would not have you believe that I use no chemicals in connection with these operations, because I and my assistant and nurses do use, for the proper cleansing of our hands, whatever chemicals are most suitable; but it may be laid down as a fixed fact that any irritating chemical introduced in solution into the cavity of the abdomen, will be eliminated through the kidneys, and imperil the life of the patient.

Time is an important factor in operations; in uncomplicated ovariotomies, I have frequently opened the abdomen, emptied and delivered the cyst, tied and burnt off the pedicle, in five minutes, spending afterwards fifteen minutes in cleaning out the abdominal cavity and closing the wound.

But a fair average time for an ovariotomy, unless it be a very complicated case, is thirty minutes.

Much has been said about the ligatures which we leave in the abdominal cavity. Thoroughly boiled silk is my choice, and on it alone I depend, using silkworm gut to close the abdominal wound.

Much has also been written about the surroundings of an abdominal operation. The weight of evidence is still in favor of the private hospital, although I believe that all abdominal operations are more safely done at present, both in and out of the private hospital, than they were five years ago. One reason of this, however, is that patients are accepting earlier interference. My experience may be unique, but I have never seen a woman die after the removal of an ovarian cyst unless she had been previously tapped.

ANTISEPSIS.

BY R. G. P. DIEFFENBACH, M. D.,
NEWARK, N. J.

Not many years ago antisepsis was an unknown part of medicine and surgery, and it has since its discovery entirely changed our methods, not only in surgery, gynecology, and obstetrics, but also in other therapeutic branches in the treatment and prevention of diseases, such as diphtheria, typhoid fever, and many others. Formerly a surgeon would not hesitate to operate for incarcerated hernia or in any other case of emergency immediately after treating a gangrenous or erysipelatous subject; the only precaution observed was to give his hands a good, and probably in many cases only a superficial, cleansing. The consequences, in the form of erysipelas, gangrene, septicemia and other similar diseases did not fail to make their appearance.

We owe the first impetus, the first system of antiseptic treatment, to Prof. Lister, and during the past fifteen years it has been improved almost daily and is now indispensable to the success in surgery and diseases in general.

It would occupy too much time to undertake to give a history of the development and describe the numberless ways in which antisepsis is used, and I will only endeavor to give a description of this mode of treatment as it is applied at the present time principally in surgery.

Antisepsis may be divided into two parts: First, the prevention of infection, called "asepsis," and, Second, the treatment of already infected wounds or tissues, called "antisepsis." In order to prevent the promotion of contagious diseases, it is first of all necessary to remove the cause and to have at all times a good supply of fresh air. A number of disinfectants are in use at the present time; the most common are: chloride of lime, solution of carbolic acid or corrosive sublimate, sulphur vapor, etc., etc. In the treatment of fresh wounds, to prevent inflammation and suppuration, the greatest care should be exercised. Cleanliness is the first and foremost part of antisepsis. For this reason, it is necessary for the surgeon and his assistants and nurses, before treating a wound or before making a smaller or larger operation or coming in contact with any part or parts which might be infected, to resort to a thorough cleansing of the hands. Brushing the nails is especially necessary, and, if an operation is to be done, the arms also. For this purpose and for the washing of sponges, Prof. Kümmel recommends the German green soap, which is extensively used in diseases of the skin, on account of its solvent properties. Then a solution of carbolic acid (about 3 per cent.) or of corrosive sublimate (1 : 1,000) should be applied. Instruments, after a careful cleansing, are to be laid in a 3 per cent. solution of carbolic acid for half an hour before being used. The patient should, if practicable, receive a bath before the operation and a thorough cleansing of the parts to be operated upon, which should be shaved if necessary, and then a solution of corro-

sive sublimate should be applied. During the operation the wound should be irrigated from time to time with a solution of corrosive sublimate (1 : 1,000 or 2,000) or with a 2 per cent. solution of carbolic acid. If the operation is in the abdominal cavity or pleura, the wound should be only moistened with a solution of corrosive sublimate (1 : 2,000). For the mouth, rectum, or bladder, salicylic acid (1 : 1,000), or boracic acid (2 : 100) are used with success; and at the end of the operation the wound may be sprayed with iodoform ether, one part to ten.

Dr. Baumann recommends an antiseptic gauze prepared by sterilizing the same in steam, at a temperature of 100° Celsius, (212° F.) or more, after which it is quickly dried in the same temperature and at once impregnated with some antiseptic solution. Smaller wounds may be dressed without sterilized gauze. Towels, sponges, sheets, silk ligatures and sutures should also be sterilized.

Prof. Bergmann claims that next to antiseptic treatment the greatest care should be exercised in regard to the bleeding and oozing of wounds, and says neglect of this care is one of the principal causes for the promotion of decomposition and suppuration of tissues and prevention of healing by primary intention. The wound should not be closed until it is perfectly dry and the smallest vessels have been tied. Drainage should be used, if the wound is not perfectly aseptic. If a wound is already infected by previous suppuration it is best to loosely tampon it with iodoform gauze, cut into strips, and the ends should be allowed to hang out of the most dependent corner of the wound. Over this an antiseptic dressing is applied without any sutures. This tampon remains for two, or, if larger vessels are oozing, four or six days. If the discharge penetrates, the outer part of the dressing is removed. The tampon is removed by gently extracting it without opening the wound, and a proper suture, with or without drainage, may then be applied.

For the dry dressing, which is much in use at present, it is absolutely necessary to have a material which readily absorbs all secretions from the wound. Iodoform, or subnitrate of bismuth in powder, or corrosive sublimate, or iodoform gauze, etc., are applied directly on the wound, then follows the absorbing material (in large quantities) such as cotton, jute or wood wool.

That antiseptic treatment is indispensable in gynecology and obstetrics is known to every practitioner. In the latter there must be absolute cleanliness of attendants as well as of the room and bed, and vaginal injections with a solution of corrosive sublimate (1: 2,000) or of carbolic acid (1 per cent.) should be used before and after labor. The use of oakum or cotton or an antiseptic pad, for the reception of lochial discharges, which can be destroyed as soon as saturated, is advisable. Intra-uterine injections of corrosive sublimate should not be stronger than 1 : 4,000 on account of toxic effects often met with. Lubricants for the fingers of the examiner should also be antiseptic.

In gynecology the same scrupulous cleanliness is necessary for operator, assistants, nurses, and instruments, and the parts to be operated upon and those in the neighborhood should be thoroughly cleansed by repeated washings and injections. The wound should be occasionally irrigated during the operation, and especially while it is being closed with sutures; frequent irrigations after operations are also necessary. Many of the German operators employ during the operation constant irrigation with a hot antiseptic fluid, of a temperature of about 120° F. The benefits derived from these are that the flow of blood is lessened, while they keep the parts clean, remove all necessity for sponging, and thereby shorten the operation.

There is yet one part of antisepsis, the importance of which is often overlooked, and this is the method of antisepsis as applied to newborn infants. It should always be borne in mind, that the act of being born is a violent insult to the integuments, above all to the head. It is only necessary to remember the peculiar anatomy which characterizes the skin of the newborn—the weak and delicate derma and the large amount of capillary and lymphatic vessels with a corresponding free circulation—to show to what a large degree infants are liable to septic influences. To prevent this, the attendants during delivery should use the proper antisepsis as already described. The umbilicus should be washed with a 3 or 5 per cent. solution of boracic or salicylic acid, and wrapped up in absorbent cotton. The use of carbolic acid or corrosive sublimate for infants is contra-indicated. For the prevention of ophthalmia Credé's method is highly recommended. It consists of putting one drop of a 2 per cent. solution of nitrate of silver in each eye.

The mouth of the infant should be washed after, and the breast of the mother before, each nursing with a solution of boric acid, to prevent the development of fungi.

These are some of the uses and methods of antisepsis to which attention may be properly called in such space as can be spared to this paper.

TURPENTINE IN AFFECTIONS OF THE THROAT AND LUNGS.

BY ARTHUR E. SPOHN, M. D.,
CORPUS CHRISTI, TEXAS.

I have been using pure oil of turpentine in affections of the throat and lungs for some time, and find better, and more satisfactory results, than from any other remedy I ever tried. I use the ordinary hand atomizer, and throw a spray of the liquid into the throat every few minutes, or at longer intervals, according to the gravity of the case. The bulb of the instrument should be compressed as the act of inspiration commences, so as to insure application of the remedy to the whole surface, which can be done in cases of children very successfully. It is surprising how a diphtheritic membrane will melt away under an almost constant spray of pure oil of turpentine. I now use the turpentine spray whenever a child complains of sore throat of any kind.

In cases of tuberculosis of the lungs, bronchitis, and the later stages of pneumonia, I have found the turpentine inhalation very beneficial. I use an atomizer, or paper funnel, from which the turpentine may be inhaled at will. I hang around the bed, and in the room flannel cloths saturated with oil of turpentine, in all cases of catarrhal bronchitis—in fact, in all affections of the air passages; and my patients invariably express themselves as being very much relieved.

—Variations in the Composition of Milk.—From the results of about 50,000 analyses made in the laboratory of the Danish Dairy Supply Company, it is found that the dry matter less fat is an almost constant value (8.7 to 8.8). The fluctuations in total solids depend almost entirely on variations of the fat. The evening milk contains more fat and more total solids than the morning milk. In October and November the milk is richer in fat and total solids than in other parts of the year.

CASE OF IDIOPATHIC TETANUS.[1]

BY W. L. COPELAND. M. D.,
CHICAGO, ILL.

G. B., 19 years old, salesman, strong, muscular, of good family history, on July 4 and 7, lay around on the grass most of the day smoking cigarettes. On July 8 he noticed some stiffness of the jaw and experienced difficulty in eating his supper. On July 9 the stiffness of his jaw increased, and about noon he called on a physician, who ordered potassium bromide. July 10 the muscles of his neck were stiff and sore, July 11 he was worse, and complained of soreness in the pit of his stomach. Three compound cathartic pills were ordered, and hydrate of chloral in conjunction with the bromide and a little nitrate of potash, as the urine was somewhat scanty. At 3 A. M., July 12, being unable to get his attending physician, I was called in to relieve the pain complained of in the pit of the stomach, which was constant, but also aggravated by severe spasms every ten or fifteen minutes. I found his pulse 140, his temperature normal, his head drawn back against the back of the chair upon which he sat. His teeth could be separated about one-eighth of an inch; his eyes were fixed; he had difficulty in swallowing and was unable to raise himself. I ordered morphia sulphate one-eighth grain, atropia sulphate one-eightieth grain and tincture of hyosciamus ten minims every hour. At 9 A. M. he had obtained no relief, his pulse was 144, his temperature 100°. Three hypodermic injections of one-quarter grain of morphia sulphate at half-hour intervals gave partial relief. Drachm doses of whiskey every hour, with a liberal supply of egg and milk, was ordered and a mustard poultice to the whole length of the spine. At noon his pulse was 110, his temperature 100°, and he was feeling easy, with only occasional spasmodic contractions of the diaphragm. At 6 P. M. his pulse was 120, his temperature 102⅕°. He was quite easy and talkative and could open his mouth about one inch. I ordered two minims of the tincture of aconite every hour until the pulse and temperature were reduced. At 9 P. M. his pulse and temperature were the same. During the night he received three hypodermics of one-quarter grain of morphia,

[1] Read at the October meeting of the Chicago Pathological Society.

but he only obtained short snatches of sleep. He passed urine freely two or three times during the night. On July 13 he had taken about ten ounces of whiskey since 11 A. M. of the 12th; his pulse was 120, his temperature 101⅗°. His skin was moist; he vomited once in the afternoon after severe spasm, then all the muscles relaxed and he slept about an hour and a quarter. He bit his tongue during the vomiting. During the day he expectorated great quantities of viscid saliva. At 8.30 P. M. his skin was drenched with perspiration.

July 15, in the morning his pulse was 96, his temperature 100°. As his bowels had not been moved for four days, I ordered three cathartic pills to be given, and then to be followed in four or five hours with enema of half an ounce of glycerine. As these failed to act the attendants on their own responsibility repeated the glycerine enema three times, and, there still being no result, three enemata of soap-suds were given, none of which had any effect except to aggravate the distress in bowels. As I was not at home when sent for, another physician was called in and two large enemata with one-half ounce of turpentine and some starch were given, and were also retained. On my arrival, about half an hour after the last enema had been given, the patient was suffering greatly, so I administered chloroform sufficient to partially relax the spasm, and dilated the sphincter ani, and a deluge followed. The patient passed a good night, sleeping the greater part of the time, his bowels moving once during the night. On the morning of July 16 his pulse was 96 and his temperature 99⅗°. July 19 his pulse was 140, his temperature 103°. He was very restless, and had general stiffness of his muscles. Atropine, one one hundred and fiftieth grain, and morphine one-quarter grain was given hypodermically. July 20 his pulse was 120, his temperature 102⅖°. A fly-blister three inches by two inches was applied to his back over the spinal column. July 21 he was about the same. He was given an enema of soap-suds which moved his bowels, his bowels were also moved during the night. July 22 I met Dr. Brower in consultation at 8.30 A. M. The patient's pulse was 130, his temperature 105°. We ordered twenty grains of sulphate of quinia to reduce the temperature. At 12.30 P. M. his temperature was 100⅘°, his pulse 128. He had one and a half hours of sleep after the quinine I ordered, the quinine to be repeated if the temperature increased. At 3 P. M. the quinine was repeated. At 6 P. M. his temperature was 103°. At midnight I was telephoned for, as the patient was wild and uncontrollable. I found him half off the bed, with hot skin, talking incessantly, and four persons trying to hold him in bed. I injected fifteen grains of antipyrine, but before I could remove the needle his struggles ceased and he dropped back dead. Rigor-mortis set in at once. About a pint of whiskey and from four to eight hypodermic injections of one-quarter grain of morphia were given daily throughout his sickness. His nourishment consisted of milk and egg-nog, and was taken freely until the last twenty-four hours.

GONORRHŒA AT FIVE YEARS OF AGE.

BY D. D. CUSTER, M. D.,
MANAYUNK, PA.

Recently a woman brought her five year old child into my office for treatment. She said that he was swollen and cried when he urinated. I examined his penis and found it very much enlarged, and to my astonishment discovered an intense gonorrhœal discharge, with a history of chordee and painful erections occurring at night. Upon questioning his mother I learned that the boy was sleeping with his sister, eighteen years old, who had leucorrhœa. The lad was extraordinarily developed and it seems to me that his disease must have been contracted by having intercourse with his sister. A lotion of lead water and laudanum was applied with absorbent cotton to the penis, and I ordered the organ to be frequently bathed in warm water. Alkalies were administered internally and other ordinary gonorrhœal remedies were used. In two weeks the aggravating symptoms subsided and the discharge ceased.

—DEAF ANIMALS.—Evidence exists that deaf mutes are not confined to the human race. In a farmer's herd for twelve years was a cow which never gave any sign of hearing, and the evident attempts of which at lowing had only resulted in a feeble guttural. Nothing abnormal could be discovered in the ears or the vocal organs.

SOCIETY REPORTS.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, October 3, 1889.

The President, ALFRED L. LOOMIS, M. D., in the Chair.

DR. C. L. DANA read a paper on the

Pathological Anatomy of Chorea,

with report of a case. The paper dealt principally with the pathological anatomy of the nervous system. Before tabulating the history of cases reported by others, Dr. Dana described his own. It occurred in a Swiss, single, eighteen years old, who entered the hospital December, 1888. He had always been weakly and sickly as a child, but gave no rheumatic, venereal, nor alcoholic history. He began to have chorea at the age of six years. He had also had so-called epileptic attacks at intervals for several years. The fits began with a shrill cry. Dr. Dana regarded these as of a hysteroid character, and not true epilepsy. He had, however, once been trephined for supposed epilepsy.

As he lay in bed he was rather dull, although he answered questions correctly. His speech was slow and jerky, owing to the choreic movements. These were so severe in general that the patient could not feed nor wait on himself. There was no heart murmur, and the thoracic and abdominal viscera seemed normal. The patient improved markedly under treatment, including doses of chloral hydrate, until in January, 1889, when he contracted pneumonia and died. The autopsy revealed evidences of pneumonia, but normal heart, without the vegetations on the valves which were so common in epilepsy. The kidneys showed some chronic changes. The skull was unusually thick, being seven-eighths of an inch in a section of the occipital bone. The pia mater was somewhat thickened; the cortex of the brain appeared normal except for very superficial softening on the under surface of both temporal lobes. The cord appeared normal. Microscopical examination was made of sections of the motor convolutions, of the temporal and biparietal lobes, and of the corpora striata, thalamus, bulb, cord, and some of the nerves. In the brain there was a slight amount of lepto-meningitis; the gray matter was considerably injected; the neuroglia was not much increased. The nerve fibres could be seen running up into the cortex, the transverse fibres of the cortex were also present. The chief changes were just beneath the cortex, the white matter here being honeycombed, the lesions being apparent in places to the naked eye. While there was no real arteritis or endarteritis, there were dilatations of the perivascular spaces, the vessel being distended by blood exudates. The process, while chronic, could not be looked upon as inflammatory, but rather as flabbiness and loss of tone of the vessel walls. At the base and tip of the temporal lobes, however, there was brain softening, and the white matter beneath was excessively honeycombed, while there was evidently an increase of the neuroglia cells. The sections of the internal capsule and adjoining part of the thalamus showed the same honeycombed appearance from vascular dilatations. Indeed in the internal capsule there were more serious degenerations, the blood-vessels seeming to fall to pieces, they were so degenerated. There was apparently some increase of connective tissue in the pyramidal tracts. The pia mater of the cord was somewhat thickened; in the cord was some congestion, the congestion being most marked in the lateral columns. It showed none of the honeycombed appearance seen in the brain and pons. In the lumbar cord a double canal was present. The anterior and posterior nerve roots showed no degenerated fibres.

There had been nearly two hundred reports of autopsies made on persons dying of chorea. He had been able to find only thirty-nine cases, however, in which a satisfactory report of the condition of the nervous system had been made; in some respects these were incomplete. They had shown that in death from chorea there were congestions, extravasations, emboli, and softening in the nerve centres; there was also much uniformity of heart lesions. It was however, only by a very minute and critical microscopical examination that much light had been thrown on the subject. Twenty-five of the thirty-nine cases were of the acute chorea of the Sydenham type, uncomplicated with insanity or other serious disorder. In only one case had no changes been found in the nervous system, and in this one Dr. Dana was disposed to think some lesions must have been overlooked. In the cases of acute chorea with insanity there was intense

cerebral hyperemia and thrombosis, with minute hemorrhages, much as in the uncomplicated cases. In chronic chorea, of which five autoposies had been made after a duration of the disease from four to twelve years, there was dilatation and thickening of the arterioles, with necrotic tendencies, spots of sclerosis, fungous growths along the vessels in one case; the cord somewhat similarly involved though to a less extent.

A study of the cases led to the belief, he said, that we were not very far from obtaining an anatomical basis for chorea. In the acute types there was hyperemia of the brain and of parts of the cord; in the brain it was not meningeal, but affected the deeper parts. It was more than an ordinary congestion. The arterial walls were paralyzed, dilated, badly nourished, and an exudation took place, the lymph spaces became distended and eroded. Sometimes spots of thrombosis and of softening of the vascular walls gave way, and there were small hemorrhages. On the other hand, the lymph spaces around the ganglion cells and neuroglia cells were not dilated, and there was no proliferation of connective tissue cells, no distinct sign of inflammation; the process was one of vasomotor paralysis. In the older cases the vascular changes were more marked.

In connection with the pathology, and in order to better understand it, the author spoke of the theories regarding the etilogy of the disease. The principal ones which had been advanced were the humoral, the embolic, the subinflammatory, the functional or agnostic, and the infectious theories. It seemed to him that there were three things at least well determined in chorea, viz., the existence of an abnormal state of the blood, an intense cerebral hyperemia in certain parts, and a neurotic history.

The dissussion was participated in by Drs. Gray, Starr, Putnam, Jacobi, Birdsall, the President, and the author. It turned largely on the theories of the causation of epilepsy, particularly that regarding infection, which seemed to Dr. Starr and the president as probable in some cases since in so many there was a history of rheumatism and cardiac complications which were believed to depend on microorganisms. Dr. Starr thought, however, that some cases at least must be of functional origin. Dr. Birdsall said the pathology given by Dr. Dana was very interesting, but it was a question whether the chorea was due to such lesions, or whether a functional disturbance manifesting itself as chorea did not end in the lesions. He was disposed to entertain the latter view.

PERISCOPE.

Lumbar Hernia.

Dr. J. Hutchinson, Jr., contributes to the *Brit. Med. Journal*, July 13, 1889, an interesting paper on lumbar hernia, in which he says:

It will be admitted that any contribution to our knowledge of this comparatively rare form of hernia is worthy of record, since there are several points about it which are still doubtful. It is generally assumed that the small triangular space bounded by the external oblique and latissimus dorsi muscles, and the crest of the ilium (Petit's triangle), constitutes a relatively weak spot in the abdominal wall, that hernial protrusion may here occur, but that strangulation of the contained intestine is very unlikely to develop. Indeed, almost the only record of an operation for strangulated hernia in this region which we possess dates from as far back as 1738 (Ravaton's case), since in Mr. Edmund Owen's case the rupture was neither strangulated nor obstructed. To Mr. Owen, so far as I can ascertain, belongs the credit of having performed the first operation for radical cure of a lumbar hernia. There is singularly little evidence as to the anatomy of this form, and what there is hardly confirms the current view that the presence of Petit's triangle accounts for the development of the hernial protrusion. No specimen had hitherto been shown at the Pathological Society; and I believe the one which I was able to exhibit there a few weeks ago, through the kindness of Dr. Stephen Mackenzie, is the only dissection of a lumbar hernia in existence in London. It was obtained from an elderly and rather emaciated man, who died (from other causes) in the London Hospital; the hernia was about the size of one's fist, was situated in the left lumbar region lying over Petit's triangle, and extending nearly from the last rib to the iliac crest, and it had existed for some years. It could be made to markedly diminish on pressure, was resonant to percussion, and had an impulse when the patient coughed. Gurgling could be detected when reduction was made, the swelling returning when the pressure was taken off. It caused the patient no pain, and

hardly any inconvenience. I was naturally inclined to think that the hernia protruded through the orthodox triangle, but found, on dissection, that this was not the case, as the aperture, which would admit two fingers and was circular in shape, was really situated above and to the inner side of the triangle. The protrusion was, in fact, just outside the quadratus lumborum, through the transversalis aponeurosis and the latissimus dorsi, where the latter arises from the strong fascia covering the erector spinæ. Another interesting feature at the *post-mortem* examination was the absence of any peritoneal sac. The looseness of the attachments of the peritoneum in this region is well known, and is taken advantage of in certain operations, such as removing the kidney through a lateral incision. It was quite easy to make the peritoneum, by gentle pressure, protrude into the centre of the hernial tumor, and, as it was certain that it had habitually during life contained intestine, it is obvious that every time the latter was reduced the peritoneal sac must have returned with it into the abdominal cavity. Whether this feature has been present in other cases of lumbar hernia it is impossible to decide, but it is one rarely met with in connection with the more common varieties of rupture.

What part of the intestine was present during life in the hernia I was unable to decide; the descending colon lay just to the inner side of the aperture, but it is quite probable that some coils of small intestine really protruded. The fact that this can occur is proved by Ravaton's case, and that omentum may form part of the contents was also demonstrated in Baron Larrey's case. But it is no doubt true, as suggested by several writers on the subject, that the colon (ascending when the hernia is on the right side, descending when on the left) is the most usual part of the abdominal contents to protrude in this region.

With regard to the coverings of a lumbar hernia it might be expected that the outer part of the sac would contain some part of the internal oblique and the transversalis aponeurosis, for the muscular fibres of the latter cease externally to the usual site of the hernia. But such little evidence as we possess on the point does not confirm this view, for in the cases in which an incision has been made there is no mention of any muscular fibres being cut through. In my case the sac was really formed by a local hypertrophy of the subperitoneal fat which had insinuated itself through the aponeurosis and muscles, and had thus come to form a tumor the size of an orange in the subcutaneous tissue. I have demonstrated the mode of development of fatty herniæ in the femoral, inguinal, and umbilical regions by a series of preparations shown at the Pathological Society. It is certain that this mode of origin of hernia (the protrusion of subperitoneal fat followed by the descent of a peritoneal sac, and sometimes of intestine) is more common than one would be led to suppose from the ordinary text-book accounts, and it was especially interesting to me to find the same thing occurring in the lumbar region. It is probable that the cases reported by Marmisse, Auzias-Turenne, Gosselin, and Marquez, were of the same nature. Out of the twenty-nine cases of which I have abbreviated the records, sixteen (over 50 per cent.) developed spontaneously, or were attributed to strain, and all of them were in adults or elderly subjects. Males and females appear to be equally liable to lumbar hernia; seven cases of this class (of apparently spontaneous origin) were on the left side, four on the right.

In six cases (about 20 per cent.) the hernia followed in the track of a previous abscess or sinus, four in males and two in females. An ingenious suggestion has been made that the path which the protrusion takes may be determined by the course of a nerve, especially perhaps the lowest posterior lumbar branch, and this may apply to the original abscess, which leads later on to the hernia.

In five cases the hernia was due to wound or other severe traumatism of the loin, and two were said to be congenital. About the origin of the last form of lumbar hernia we are absolutely in the dark, for there is nothing in the development of the abdominal wall that explains the formation of a gap in the lumbar region.

For practical purposes we may say that the spontaneous form of lumbar hernia is confined to the period of adult life or old age, whilst that due to abscess or traumatism may occur much earlier.

It is quite erroneous to attribute to M. Petit the first account of lumbar hernia. It was mentioned by Barbette so long ago as 1650, and several cases were reported before M. Petit's very imperfect record was published in 1783; nor, as already mentioned, is there strong evidence that in the majority of cases the

protrusion occurs through the triangle named after the French surgeon. Mr. Edmund Owen states that in the child on whom he successfully performed a radical cure the protrusion was at this site; but in the two other cases, in which one can feel certain on the point the triangle was not the seat of the hernia; in the former case it did not exist. As is well known, the latissimus dorsi and external oblique may be in close apposition at their attachments to the iliac crest; and Lesshaft, by examination of a considerable number of bodies, determined the fact that Petit's triangle was nearly always wanting in young children, and in about every fourth adult man. In grown-up women, however, it is practically constant. To those interested in the literature of lumbar hernia, Baron Larrey's and Dr. Braun's papers may be commended as giving the most complete account of the subject.

It only remains to say a few words as to diagnosis and treatment. With regard to the former, the mistake which has occurred most often has been to suppose that the hernia was a chronic abscess, and in Dolbeau's case the intestine was actually incised and a fecal fistula formed, which, however, ultimately healed. The absence of true fluctuation, the probable resonance, and the reducibility of the swelling, should serve to prevent such an unfortunate mistake. Other erroneous diagnoses that have been made are hernia of muscle, sarcoma, and hæmatoma: but it is unnecessary to do more than mention these. With regard to lumbar hernia, as is the case with most rare diseases, the knowledge of its possible occurrence is the first and the chief step towards a correct diagnosis. That in more than one case the swelling has been at first called a lipoma is not surprising, since it is probable that the hernia, in a fair proportion of cases, has actually consisted in a protrusion of the subperitoneal fat. At any rate, this view is supported by the example now brought forward.

With regard to treatment, the use of a well-made abdominal belt nearly always suffices, but one may safely conjecture that Mr. Owen's case will be followed by others in which a radical cure is effected by operation. It is a curious fact that Ravaton's case, reported more than one hundred years ago, remains the only one in which there is a clear history of operation for strangulation, though one or two others have been recorded in which this complication has occurred.

Massage of the Eye-Ball.

Mr. Simeon Snell, in an Address, published in the *British Medical Journal*, July 13, 1889, says:

A mode of treatment which has come much into vogue in both medical and surgical practice in recent years has also found its uses in ophthalmic cases; I refer to massage. It is true that there is not scope for the many refinements under various names with which massage has beset itself. The mode of employment as advocated on the Continent and in this country by myself is very simple. It consists in rubbing gently, in varying directions, to and fro, and in a more circular manner, the eyelids over the eye-ball. The friction may be concentrated chiefly on one spot or be more general, and the surfaces of the eyelids may be rubbed together. Usually a lubricant is used, and vaseline answers this purpose; but, especially in corneal and conjunctival affections, which are so often well treated by massage, the yellow oxide of mercury ointment, made with vaseline, is to be preferred, the value of the ointment and of the massage being made use of at the same time. Time compels me only to mention in the most general way the cases for which this method is applicable. Corneal and conjunctival affections, chiefly in chronic, but often in acute cases, derive great benefit from massage; generally they should be free from irritability. In the often obstinate cases of perisclerititis it is frequently of great service.

Dr. Mules not long since recorded a case illustrating the value of massage in a recent instance of embolism of the central retinal artery; vision was recovered.

A class of cases has much interested me. I refer to traumatic cataracts, and I include among these soft cataracts which have been needled. I have no doubt that in many cases the process of absorption is decidedly promoted by massage. It should not be adopted until the eye is tolerably free from irritability. If the opening in the capsule is at all free, softened portion of lens can often be massaged out of the capsule into the anterior chamber, and any portions already there can be moved about in the aqueous. More recently I have made use of massage as a means of ripening immature cataract, especially in cases in which Forster's operation for maturation has not produced such a rapid development as could be wished. In others the anterior chamber

may be tapped before commencing the massage. My experience is too limited at present to speak as to its value in these cases.

Some years since I met in the street an old infirmary patient who had undergone successful cataract extraction in one eye. I asked when he was coming to have the other eye operated upon. He replied he was "rubbing it off." When I desired him to come and see me when he had rubbed it off, I little thought that I should be advocating massage as a means for promoting absorption, at all events, of traumatic cataracts, or, as my friend would have called it, "rubbing it off."

Nephrectomy of a Horseshoe Kidney.

Professor Socin, of Bâle, performed an exploratory operation last year on a woman, aged 47, who had been subject for thirty years to pains in the right hypochondrium, where a tumor had gradually formed. He aspirated, and found that the swelling contained urine; then he performed nephrotomy. Hydronephrosis was discovered during the operation. The urine passed by the urethra remained normal, but on and after the fourth day an abundance of turbid urine drained from the opening made in the kidney, and an examination led to the conclusion that parenchymatous nephritis and purulent pyelitis were present. On May 12 nephrectomy was attempted. After an abdominal incision and successful ligature of the structures in the hilum, it appeared that nothing was left to do besides setting free the lower part of the diseased kidney. On careful manipulation this extremity was found to be continuous with a bridge of renal tissue, which passed over the aorta and vena cava and joined the lower part of the left kidney. This bridge or isthmus was found to be but loosely connected with the great vessels. Dr. Socin divided it by means of the thermo-cautery, so that the right side of the horseshoe kidney came away. Five ligatures were applied to bleeding points on the raw surface left behind, which was then covered over by the capsule, the edges of the latter being united by sutures. An abdominal-lumbar drain was applied. The patient was in excellent health four months after the operation. In Braun's (Heidelberg) similar case a horseshoe kidney was discovered at operation for the removal of a pyonephrosis. The isthmus adhered strongly to the vena cava; on attempting to separate them, profuse venous hemorrhage occurred, which was controlled with difficulty. The patient sank from exhaustion at the end of the operation.

A Drainage-Tube Passed Through the Rectum.

Dr. Mariani describes in the *Siglo Medico* a case where a rubber drainage-tube was passed into the abdominal wound after the removal of a large dermoid cyst which adhered to the parietes, the omentum, and the liver. The patient was 46 years old. The wound healed in a week, but the tube had been allowed to slip into the abdominal cavity. The patient complained of pain referred to the left anterior superior iliac spine. A week after the healing of the wound the tube was passed during defecation. It had probably caused inflammation of the adjacent large intestine, and passed through the softened walls of the gut. About twelve years ago an entire stump of an ovarian pedicle was passed at stool. The case occurred in Germany, and the patient recovered. The expelled body must have entered the intestinal canal in the same manner as in Dr. Mariani's case.

Indications for Operating on Disease of the Mastoid.

In the *New York Medical Journal*, May 25, 1889, Dr. Charles H. May gives an account of his experiences at the Aural Clinic of Prof. Hermann Schwartze, of Halle, Germany, who is a great authority on diseases of the mastoid. The indications for opening the mastoid, according to Schwartze, are:

1. Acute inflammation of the mastoid with retention of pus, if the application of cold by the ice-bag or coil and the performance of Wilde's incision have failed to cause the œdematous swelling, pain and fever to disappear. In children the palliative treatment may be tried a little longer, but in adults a delay until pyæmic or meningitic symptoms set in he considers decidedly. For, if doubt exists, it is better in his opinion to err by performing an operation which is now almost devoid of danger

to life. Even if no pus is found, the operation may be and often is curative in checking the further progress of the inflammation.

2. In chronic inflammation of the mastoid, where repeated attacks of swelling with consequent improvement have taken place, or where there has been the formation of abscess or fistulæ pointing or opening at or through the skin of the mastoid region, the neck, auditory canal or pharynx. The operation is recommended in these cases, even though there is no immediate danger of life, for in such cases surgical interference is less dangerous than the results of a continuation of the chronic inflammatory process.

3. In cases in which, although the mastoid appears healthy, externally, there is retained pus or cholesteatoma of the middle ear which cannot be evacuated by the natural channel, as soon as symptoms appear which indicate that complications dangerous to life are imminent.

4. In cases of long-continued pain in the mastoid region, although the bone is apparently healthy, when the pain is not controlled by other remedies. Here the chiseling of a funnel-shaped or boat-shaped piece of bone from the sclerosed cortical portion of the mastoid may effect a cure without the necessity of extending the opening into the antrum.

5. As a prophylactic measure against the fatal consequences which might ensue as a result of incurable purulent inflammation of the middle ear with fetid discharge, in cases in which there are no other symptoms of retention of pus in the middle ear, except an obstinate penetrating fetor of the pus, despite careful cleansing and disinfection through the auditory canal and the Eustachian tube. In these cases the antrum is opened and kept open for a time, in order to permit washing out of the middle ear from behind.

Large Families.

One of the New York papers having offered a prize to the Metropolitan mother who had successfully reared the largest number of boys and girls, quite a number of claimants with a dozen children appeared and a few with fourteen. But the prize was carried off by the mother of fifteen children, all living, the youngest being five years of age. The father of this interesting family was one of fifteen children, some of whom have died, but the mother is one of fifteen, all of whom are living, some of them at advanced ages. The story developed by the prize offer is interesting, in view of the alleged deterioration of the human stock.—*Ledger*, Sept. 9, 1889.

Medical Aid Stations in Berlin.

The Berlin correspondent of the *Medical Age*, June 10, 1889, says that in Germany, especially in the metropolis, every city has provided for hundreds of medical aid stations —one in every four squares or so—where experienced medical services can be commanded in case of emergency. This institution is a blessing, especially at night, and is of equal service to the poor and the rich. The town pays for the medical officers, who are not at liberty to accept fees. The subject is of sufficient importance to engage the attention of the municipal guardians of American cities.

Congenital Chorea.

M. Michon showed at the March meeting of the Society of Medical Sciences in Lyons an infant suffering with congenital chorea. The infant, a male, was born at full term, and since birth has exhibited rhythmic convulsive movements of the muscles of the face and limbs. Its mother had suffered from an attack of "brain fever" at four years of age, and with regard to its grandmother, there was a history of convulsive attacks with contractions.—*Medical Press and Circular*, June 12, 1889.

Antipyrin, Antifebrin, and Phenacetin in Whooping-cough.

Dr. Leubuscher, of Jena, states in the *Centralblatt für klin. Medicin*, No. 7, 1889, that Sonnenberger, who was the first to recommend antipyrin as a specific in whooping-cough, has gone too far in his estimation of the remedy. When administered early, antipyrin is unquestionably capable of influencing the course of whooping-cough, both in its intensity and duration, so that in some cases the whole disease is passed with at most six or seven attacks of less intensity in the twenty-four hours, and ceases entirely after three or four weeks. On the other hand, however, Leubuscher was in no case either able to abort whoop-

ing-cough with antipyrin, or, by administering it as a prophylactic to a child whose brothers and sisters were ill with the disease, to prevent an outbreak of it. In the height of the disease antipyrin is of as little service as the other remedies.

Leubuscher has obtained as favorable results from the cheaper antifebrin as from antipyrin; but on account of the danger of continuous administration of antifebrin he cannot unconditionally recommend it. The author found phenacetin completely inactive.—*Deutsche Medizinal-Zeitung*, July 1, 1889.

Mustard Plaster.

Never place a cold mustard plaster upon a patient. The shock is like a sudden plunge into cold water. Before you commence to mix the paste be sure you have all the necessary material at hand. First put a large plate where it can get warm, not hot. Then stir the mustard and flour thoroughly together before you add the water, which should be tepid, stir in enough water to make a paste about the consistency of French mustard. Place your cloth (an old handkerchief is best) on the warm plate, spreading the paste in the middle of it, leaving a margin wide enough to lap well over on all sides. Do not remove paste from the plate until ready to apply. Place a folded cloth between paste and patient's clothing.—*Trained Nurse*, July, 1889.

Chloroform in Diseases of the Lungs and Heart.

Prof. O. Rosenbach, of Breslau, states in the *Internat. klin. Rundschau*, No. 1, 1889, that a very large experience has persuaded him of the efficacy of inhalations of small quantities of chloroform in some cases of diseases of the lungs and heart. These are the cases in which one has to cut short relatively brief and frequent attacks. There is one advantage in inhalations of chloroform, that the physician can stop the inhalations at will and so have control of the dosage of the narcotic. They are especially active, he says, in the attacks of dyspnœa occurring in patients with heart disease and emphysema, in the frequent paroxysms of cough of phthisis, and often also in hiccough and in certain neuralgic disturbances of the heart.

In giving the inhalations, the author drops from seventy-five to ninety minims of chloroform upon some cotton in a funnel, and the patient is allowed to inhale the vapor slowly. The cone is not held too near, so as to allow an abundant supply of atmospheric air to enter the cone. The patients, he says, soon attain a certain degree of comfort or fall asleep, to awake in an hour strengthened. Even attacks of œdema of the lung can be aborted by it. Finally, the author recommends chloroform and the less irritating chloroform water as an analgesic and antiparasitic remedy for application to the parts of a larynx affected with tuberculosis.—*Deutsche Medizinal-Zeitung*, June 20, 1889.

Iodoform in Hemorrhage.

In the Bulgarian bi-weekly *Meditzinski Preglëd*, Nos. 3 and 4, 1889, Dr. Mikhaloff, of Sophia, the editor, publishes a very interesting paper in which he highly recommends the internal administration of iodoform, in the dose of three-fourths of a grain five times daily, as an excellent remedy in hemoptysis, hematuria, menorrhagia, metrorrhagia, flooding after abortion, intestinal hemorrhage (including that of typhoid fever and tubercular ulceration of the bowels), bleeding from hemorrhoids, etc. He adduces a long series of instructive cases treated with the remedy, and adds that Dr. L. Serafimoff, of Sophia, also obtained most gratifying results from the drug in several cases of metrorrhagia and obstinate profuse bleeding from the nose. In conclusion, Dr. Mikhaloff suggests a trial of the remedy in dysentery, in which iodoform may prove beneficial, not only by virtue of its hemostatic power, but also as a disinfecting agent capable of checking any putrefactive processes in the intestinal contents.

Rapid Rotation of the Head in Occipito-Posterior Positions.

M. Budin calls attention to the fact that sometimes the fetal head, when in an occipito-posterior position, will perform rotation so rapidly that the occiput will come under the pubic symphysis while the limbs and body have not yet turned, so that the back of the head faces the anterior portion of the body of the fetus. In one case given, in which version was intended, the hand in-

troduced into the uterus to search for the mouth found it only by following the posterior plane of the body. M. Ribemont made sections of the frozen fetuses, which had first been put into a state of forced rotation as above described, and he found that the rotation took place not only in all the cervical column, but also in the dorsal region down to the seventh dorsal vertebra. On account of this known action, it was proposed to employ the forceps in occipito-posterior positions when the head arrived at the perineum and the rotation was not accomplished. Dr. Budin was lately able to make this new application of the forceps with complete success for the mother and child, and thus to give a practical demonstration that there may be a considerable degree of rotation of the fetal head, and that an accoucheur can bring about this movement in certain cases, without fear of a dislocation of the cervical column and death of the fetus.—*New York Medical Journal*, April 26, 1889.

Pathogeny and Metastasis of Eczema.

M. Gaucher states, in a communication to the *Bulletin Médical*, September 1, 1889, that it is often dangerous to cure eczema, especially in children. He thinks that the exaggerations of the anatomical school and of parasitic doctrines have caused the part played by humoral alterations in cutaneous affections to be completely forgotten. Something is known of chemical alterations of the blood and humors in diabetes, in gout, and in uremia; and in all these diseases metastases are observed which, according to the facts of contemporary science, can be called chemical metastases. Hence, in patients affected with eczema, he says, we may suspect the existence of toxic principles which are eliminated by the skin, which thus acts as a safety-valve. The toxic principles are the products of mal-assimilation. If the skin affection is suppressed, the toxic matter may accumulate in the internal organs and determine more or less rapid and more or less grave accidents, according to the seat of the metastasis. These accidents should be more frequent in children because of the greater activity of their nutrition, which leads to an easier displacement of toxic matter, and because of the delicacy of their organs; they should be graver in children because their resistance is less.

Gaucher gives nine observations, which appear to confirm his theory. He concludes that in old persons and in children much circumspection should be exercised in the treatment of eczema, especially if it is very extensive. The whole diseased area, he says, must not be treated at once, but it should be attacked in successive fractions. Too energetic topical applications should not be employed. It is necessary to proceed slowly, in order to habituate the organism, in some degree, to the suppression of the cutaneous emunctories, and to give time to the toxic principles to be eliminated little by little by the intestine or kidneys. In his opinion, it is even necessary to provoke this substitution of emunctories by the administration of purgatives, and of diuretics, of which, he says, milk is certainly best.

Death from Rattle-snake Bite.

It is very seldom that a death from rattle-snake bite is actually recorded; but the daily papers of October 1 report that a postal clerk on the route between Melbourne and Jupiter Inlet, Florida, died September 29 from the bite of a rattle-snake. About midnight of the day before he accidentally stepped on the snake as he was walking along the highway, and the reptile buried its fangs in one of his legs. He twisted a handkerchief about the wound and hurried to a physician. The wound was cupped and poulticed, and whisky administered freely, but the treatment proved unavailing.

Chloralamide, the New Hypnotic.

Dr. E. Peiper communicates to the *Deutsche med. Wochenschrift*, No. 32, 1889, an account of the experiences at Mosler's clinic with chloralamide. It was given in the form of a powder, in doses of from 15 to 45 grains, with 15 grains of elæosaccharum of fennel (a mixture of oil of fennel, one drop, and sugar, 15 grains); or in capsules, to be followed with a drink of milk, water, or coffee. It was frequently also given in a mixture:

℞	Chloralamide	gr. xlv
	Acidi hydrochlor. dil.	qtt. v
	Aquæ destil.	f℥ ii
	Syr. rubi Idæi	f℥ iiss

M. Sig. To be taken in one dose.

Wiener med. Presse, August 25, 1889.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

AMYLENE HYDRATE IN EPILEPSY.

New and effective remedies in the treatment of epilepsy are very much needed. From time to time many such have been suggested; but the hopes inspired by the assertions of their advocates have been dashed to the ground. Amylene hydrate is one of the most recent claimants for favor. In the *Neurologisches Centralblatt*, No. 15, Dr. H. A. Wildermuth, of Stuttgart, has an interesting communication giving the results obtained by him in sixty-six cases of epilepsy which were treated with amylene hydrate. From the *Wiener med. Presse*, August 25, 1889, we gather that the patients were about equally divided as regards sex, thirty being men and thirty-six women. The result is stated to have been favorable in the majority of the cases, and in some instances the disease seemed to be absolutely aborted. As regards the quantity of the drug given, Wildermuth says that from thirty to forty-five minims were given at a dose, or from seventy-five to one hundred and twenty minims in the day. After a number of trials it was found most suitable to make a watery solution of the amylene hydrate, of the strength of one part in ten, of which solution from five to ten teaspoonfuls were given at a dose, in diluted wine or fruit juice. The character of the disease appears to have offered a severe test of the efficiency of the remedy; for with one exception the patients had been affected with epilepsy for years, and had been previously treated for a long time with bromides—the bromide of potash alone, or a mixture of the salts of bromine. In addition to the bromides, most of the patients had also received atropine, or pills of zinc and belladonna. The administration of the pills was discontinued immediately upon beginning the amylene treatment. The bromides, however, were not stopped at first, but were only lessened in quantity at very short intervals; and if, in spite of this, the favorable result apparently due to the amylene hydrate continued, the bromides were no longer given in any amount.

The results appear to be of special interest in cases in which there were a number of attacks at one time, which by other means we are often powerless to overcome. In such cases, Wildermuth states that one or two subcutaneous injections of the drug were found preferable to its administration in any other way. No bad secondary effects of any kind were observed in the employment of the drug in the manner described in the *status epilepticus;* but when it was used for a longer time in larger doses, some disagreeable symptoms occurred which deserve special mention. In the first rank is to be named deep persistent somnolency, which in certain cases set in, in a wholly unaccountable manner, even after small doses. This often ceased spontaneously after the patient had become accustomed

to the amylene, and did not necessitate a diminution of the daily dose. Administration of the remedy in more appropriate dose, and regular mid-day rest, were found of assistance in accustoming the patient to the action of the amylene. If this result was not secured, but the favorable action of the drug upon the epilepsy still made its repetition desirable, small doses of cocaine —one-third to five-sixths of a grain—given internally, were found to have a good effect in overcoming the somnolency. Rarer secondary effects than somnolency were digestive disturbances, constipation, and deficient appetite. These, he says, may also disappear spontaneously, or upon the administration of doses broken as much as possible. Wildermuth, however, declares that he has never observed continuous disturbance of the digestive functions.

An objection to the prolonged administration of the amylene hydrate—for months or years—is the fact that, in many cases, its anti-epileptic action ceases after six or eight weeks, and that further increase of the dose is inadvisable on account of the increase in the bad secondary symptoms already mentioned.

Wildermuth regards the employment of the drug as indicated: first, in epilepsy characterized by frequent paroxysms; second, whenever a patient shows the toxic effects of a bromine compound, and a temporary discontinuance of the remedy appears to be indicated; and finally, in nocturnal epilepsy, perhaps in this variety alternating with a bromide or, in recent cases, with bromide and atropine. According to his observations, the effect of the amylene in pure nocturnal epilepsy appears to be better than in the cases in which the attacks occur by day or by night in a less regular manner.

It is evident from Wildermuth's paper that he does not expect amylene hydrate to replace the bromides in the treatment of epilepsy, but rather that he regards it as preferable in certain varieties of the disease, and as a substitute for them in the special conditions mentioned. The moderate tone he adopts in his praise the more inclines us to hope that other clinicians will find it as helpful as he has in the treatment of this distressing and obstinate disease.

ACID SUBLIMATE SOLUTION IN DIPHTHERIA.

Mercury is one of the oldest remedies in diphtheria. It was employed with confidence by physicians in the early part of this century, but fell into discredit at a time when it was much abused in almost all the diseases in which it was administered. In more recent years it has been recommended for internal use, especially by Dr. William Pepper and Dr. Abraham Jacobi. The latter regards it as most valuable in the laryngeal form of the disease. Mercury has also been employed in solution for its local effect; but whether used in the form of a spray, or applied directly by means of absorbent cotton and a probang, the results hitherto have not been encouraging. In the *Berliner klin. Wochenschrift*, August 26, 1889, Dr. Rennert, of Frankfort on the Main, recommends a slight modification of the method of applying the mercurial solution directly to the throat, which, he asserts, has been followed by excellent results in his own practice. The modification referred to consists in acidifying the sublimate solution with tartaric acid, as originally suggested by Laplace. The proportions of mercury and tartaric acid to the water are: bichloride of mercury, one part; tartaric acid, five parts; water, one thousand parts. In applying the solution, a wad of absorbent cotton moistened with it is held in a pair of forceps, and with this brush the false membrane adherent to the throat or tonsils is wiped off, from below upward. The author admits that it is by no means easy to clear the throat in this way; and perhaps to most persons the process would suggest scraping rather than wiping. If his statements are accepted, however, the results have been

exceedingly good: all of the sixty-two patients treated in this manner, during a period of fourteen months, recovered; fever disappeared in from one to five hours after removal of the membrane; and the only complications observed were, in one case each, inflammation of the middle ear, paralysis of the palate, strabismus, and very slight inflammation of a number of joints. It should be stated that when the membrane removed was deep seated, an ulcer was left; this it was found advisable to touch with the solution morning and evening until the fever subsided. No other local treatment was employed than the one described; but the author states that he willingly permitted the patients to suck oranges, in order that an acid reaction might be maintained in the pharynx.

The method described has much to recommend it on theoretical grounds: corrosive sublimate is probably a most efficient germicide and disinfectant, and the addition to it of an acid makes it more penetrating; and, therefore, its employment in the removal and destruction of the false membrane in diphtheria should prevent subsequent infection. But practically there are serious objections to its use in the way proposed. Most cases of diphtheria occur in young children, who do not co-operate with the physician and cannot be expected to. As a matter of fact, they usually make so great resistance to much milder local measures that the physician is obliged to desist from attempting them, lest the struggles of the little patient result in dangerous exhaustion. Moreover, the method is not applicable to cases in which the membrane is so extensive that it cannot all be removed. This Rennert himself admits. Any membrane left would serve as a fresh focus of infection. We may venture to conclude, therefore, that—if the experience of other observers confirms the results obtained by Dr. Rennert—the local use of an acid solution of corrosive sublimate will be found of service in cases of diphtheria in older children and in adults, when the membrane is not too extensive to be removed entirely.

TREATMENT OF BURNS WITH IODOFORM GAUZE.

It is desirable in the treatment of burns to have a dressing that is dry; that will tend, at least, to prevent decomposition of the discharges; and that is anodyne. In extensive superficial burns a dressing of patent lint wet with carron-oil, followed, when the acute pain is over, by oxide of zinc ointment thickly spread on some soft material, gives excellent results. But the combined odors of the oil and of the discharges from the burn are offensive to most persons. At the meeting of the Congress for Dermatology and Syphilis, at Paris, August 5 to 9, 1889, Dr. Schiff, of Vienna, spoke of the treatment of burns with iodoform, which had been previously recommended by von Mosetig. Dr. Schiff asserts, according to the *Wiener med. Presse*, August 18, 1889, that iodoform lessens the violent pain felt in burns, and brings about a speedy recovery. According to the method he recommends, before the iodoform is applied, the blisters are removed and the burned surface is washed gently with cotton soaked in a one-half per cent. salt solution. Several layers of iodoform gauze are then laid upon the burn, a piece of gutta-percha is laid over them, then a layer of absorbent cotton is applied, and the dressing is held in place with a bandage. If the discharges from the burn soak through the dressing to the bandage, the latter and the cotton are changed; but the iodoform gauze is allowed to stay on until the end of the first or the beginning of the second week. Mosetig recommends that no water-proof material should be employed for the outer dressings, as they result in needless maceration of the granulations. When the burn is on the face, he recommends an ointment of iodoform, of a strength of one part to twenty, over which a mask of gutta-percha is placed. The dressing should be renewed daily.

Schiff states that he has treated in this way one hundred and nine cases of burn, some of them very severe, and has obtained a cure in most cases. If the gauze is properly applied, he says that no poisoning occurs even when the burn covers an extensive area. Hebra, of Vienna, was more reserved in his statement as to the good effect of iodoform; he said that he had seen good results from it at the beginning when the scabs had not separated; but after they had come away he thought the iodoform hindered the skinning over of the granulations. When this is the case, he asserted that resorcin in one or two per cent. solution, caused a rapid production of epithelium.

Those who have been successful in the treatment of burns by a certain method naturally will be very slow to change it for another; but it is always well to have more than one good method to which recourse may be had to meet the requirements of any case, or even to suit the preferences of the patient. In the present case, iodoform gauze will make an aspetic dressing, and if it can, as Schiff and Mosetig say, be left on for a week or more, much discomfort and actual pain will be saved the patient. Moreover, this dressing is clean and is easily applied. We think it is worthy of a fair trial at the hands of surgeons and general practitioners in this country.

A MEDICAL PLAGIARIST.

The *New York Medical Journal*, October 12, 1889, contains an Editorial making appreciative reference to an article which was published in the *Pacific Medical Journal* for September, entitled "Gynaia—A Review." This article is exceedingly amusing, and would be very creditable to the supposed author, who modestly hides his personality under the *nom-de-plume* of "Figulus," were it not for the important fact that he stole it —almost word from word and point for point —from an Editorial in the N. Y. *Times*, about ten years ago—July 8, 1878. It is likely that "Figulus" hoped this fact would not come to the notice of the readers of the *Pacific Medical Journal* on the Western coast of the United States, but he ran a little risk on the memories of its readers in the East.

We sincerely trust there is nothing more than a coincidence in the fact that the word "Figulus" means a potter, and that one of the collaborators, named on the title-page of the *Pacific Medical Journal* is Lewis Potter, A. M., M. D., Professor of the Theory and Practice of Medicine in Cooper Medical College, San Francisco.

TREATMENT OF BRIGHT'S DISEASE.

Among the various methods proposed for the treatment of Bright's disease, one of the most recent is that of a prolonged stay in a room with a very high temperature. This method, which was proposed by Dr. Luton, of Rheims, in August of this year, appears to be rational, and it certainly gave a good result in a case in which he watched its effects. It takes advantage of the intimate relation which exists between the skin and the kidneys in the function of excreting water. If patients with albuminuria, dropsy and a disposition to uremia are kept in a room with a temperature of 95° Fahr., a condition is provided appropriate to their sensitiveness to cold, while their defective excretion of urine is made up for by perspiration, the kidneys diminish their functional activity, and, under the influences of this relative rest, gradually return to their normal condition.

A small room, a quiet bed, a stove and a thermometer are all that is necessary. The degree of warmth must be such that the patient will be kept always on the border between perspiration and moisture of the skin. The principal part of the treatment is the constant staying in moderately warm and dry air. The method entails some discomforts in attendance upon the patient which, for the most part, can be obviated by having a window in the door.

Dr. Luton learned this method of treatment by accident. A woman who was affected with Bright's disease passed through different methods of treatment unsuccessfully, and then went to the Hôtel Dieu. Dr. Luton was always astonished when he entered her room to find how extraordinarily warm it was—at a temperature of 95° Fahr. While he himself felt very uncomfortable, the patient was very well and was scarcely noticed to sweat. There was no occasion to change the treatment; the patient recovered, the œdema subsided, and the albumin disappeared from her urine. After a month the temperature of the room was gradually lowered, and after a second month the woman left the room cured. Since more than a year the patient has returned to her usual manner of life and has enjoyed the most complete health.

This case is reported in the *Deutsche Medizinal-Zeitung*, May 23, 1889, and it would be interesting to know if another patient, subjected to such a temperature intentionally, would bear it as patiently, and secure as good results from it.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

INEBRIETY: ITS ETIOLOGY, PATHOLOGY, TREATMENT AND JURISPRUDENCE. By Norman Kerr, M. D., F. L. S., President of the Society for the Study of Inebriety, etc. Second edition, 8vo, pp. xxxii, 471. London: H. K. Lewis, 1889.

Dr. Kerr makes a strong appeal that inebriety should be recognized and treated as a disease, not as a vice or as a crime. This appeal is directed more to the sympathies of his readers than to their reason. In reading over the chapters treating of the predisposing and exciting causes of inebriety, we are led to think that, in the author's opinion, almost anything may serve as a cause. He cites the case of a clergyman: "Learned, studious, self-denying, he is an active and energetic worker in the service of his Master. . . . . Under the influence of some sudden nervous shock, or, as I have also seen, through exhaustion of brain from excessive toil and worry, his nervous system is shattered, he is completely crushed, and (it may be medically) takes an occasional alcoholic stimulant. He feels refreshed and reinvigorated for the renewed performance of the duties which lie so near his heart. . . . . Insensibly he is drawn closer and closer within the fascinating, narcotizing, physical embrace of alcohol"—and then, of course, degradation is rapid. No one will deny that a clergyman—or any other man—who becomes a drunkard is diseased, and that he should receive medical treatment with a view to restore his wrecked physical condition and to strengthen his weakened will power and moral sense; but—apart from the palliating circumstances, which Dr. Kerr records with such a sympathetic touch, which explain and excuse but do not justify the act—the case is simply one in which a man yielded to temptation, ignored the consequences, and became a drunkard. He became a diseased man, but the act which made him such was not caused by disease. This distinction Dr. Kerr does not make.

In the treatment of the majority of cases, especially at the later stages, the author thinks there is nothing equal to a "lengthened abode" in a genuine or well-conducted home or retreat for inebriates. The book concludes with a good account of the laws affecting the inebriate.

The book is a special plea rather than a sound argument in favor of the author's thesis. It is interesting, however, and should be read by those who desire to hear all sides of the question.

BOOK ON THE PHYSICIAN HIMSELF AND THINGS THAT CONCERN HIS REPUTATION AND SUCCESS. By D. W. Cathell, M. D. 8vo, pp. 298. Ninth edition, revised and enlarged. Philadelphia and London: F. A. Davis, 1889. Price, $2.00.

The fact that this book has already reached a ninth edition clearly shows that physicians have felt the need of a book devoted to an explication of their relations to their patients, and to advice bearing upon the achievement of reputation and success. Dr. Cathell's book is now so well known that an extended review is unnecessary. Perhaps his readers will feel that his advice has in it too much of the wisdom of Solomon and too little of the spirit of St. Paul; but then those who feel so will be less likely to be harmed by it. The young man may perhaps put the book down with the feeling that, if the author is correct, there is more in show than in sound learning; whereas he should consider that learning may go unrecognized and unrewarded unless it is accompanied by pleasing, cordial manners and attention to all the little details which develop and maintain reputation and the success which follows it. The book is full of helpful hints, and is valuable if only for its suggestiveness.

IMMUNITY THROUGH LEUCOMAINES. By Eusebio Guell Bacigalupi. Translated from the second French edition by R. F. Rafael, M. D. 8vo, pp. x, 155. New York: J. H. Vail & Co, 1889.

The author believes that germs cause the infectious diseases—such as small-pox, fowl-cholera, cholera, anthrax, etc.; but he does not believe that the immunity which follows inoculation with the attenuated virus of the disease can be explained by the action of the microbes themselves. He has been led to this belief by a statement of Ferran's, that by habituating the nature of man to the poison produced by the microbe, he had rendered it refractory to the disease, just the same as immunity from the fatal effects of morphine is obtained by its frequent use. In this case it would not be the microbe, more or less attenuated in its disease-producing power, nor yet a similar disease, which produces immunity when inoculated; but it would be the poison generated by the vital activities of the microbe. A man supplied with abundance of food, but placed in a room hermetically sealed, will gradually

perish from the re-absorption of his own exhalations, which are poisonous to him. The same result will follow in the case of a fish in a glass-globe, supplied with water and open to the air, if the products of its life are left in the water. In other words, in all living beings the products of life are noxious to this same life. It follows, therefore, that microbes supplied with a limited amount of broth will perish from the gradual accumulation in it of their own noxious products—leucomaines; and that, if into this broth new microbes are introduced, they will die there, just as a man will die if he enters an apartment where others have already died after having absorbed all the elements of life existing therein and leaving behind the products of their own existence.

The author's theory as to the production of immunity, briefly stated, is that immunity in an infectious disease is secured by the inoculation of the leucomaine peculiar to the microbe causing the disease. This theory he supports by many ingenious arguments. The first part of the book explains the theory and the reasoning which led up to it; the second part is devoted to a demonstration of it; and the third part to an explanation of some of the phenomena of infectious diseases by the theory. The author attempts to explain how immunity may last for years, if it is due to the presence in the body of a leucomaine; but in this he cannot be said to have succeeded.

The book is an extremely interesting and valuable contribution to our knowledge of immunity. Its theory is not proved, but it deserves careful consideration; and it seems to us the best explanation of the subject yet offered. The work of the translator has been well done, but the appearance of the book is marred by a number of careless typographical errors.

DORANCE. By R. E. Nelson. 8vo, pp. 223. New York: John B. Alden, 1889. Price, 75 cents.

This book is not of the kind usually reviewed in the pages of the Reporter, but it has been forwarded by one of our subscribers with a special request for notice. It appears that the author was not twenty years old when she wrote this book, and this adds interest to what is in itself a very interesting story with an admirable purpose, namely, to illustrate the injustice and wrong of the system of black slavery which used to be a blot to the civilization of this country. The story describes the vicissitudes of a white child that was kidnapped by a bereaved slave in revenge for her own loss, and describes the execution of a sort of poetic justice against this unfortunate child. The painful part of the story is made up at the end by a happy *denouement.*

Literary Notes.

—The first number of the *Lehigh Valley Medical Magazine* is an octavo of 46 pages and cover. It is to be published quarterly by the Lehigh Valley Medical Association, and is to contain the transactions and papers of the Association, and such other matters as may be found convenient and profitable. The price is to be $1.00 a year. The first number is an admirable one, and its successors are likely to have the same character. It is not intended to compete with other medical magazines, but cannot fail to be of interest to the profession in the immediate neighborhood of the Lehigh Valley. The enterprise will have, we are sure, the best wishes of the already established medical publications.

Correspondence.

Telephone Probe.

To the Editor.

Sir: If you can spare the space in your journal, I wish to discuss an invention called "the telephone probe," described in the Reporter of Sept. 28. Will this "telephone probe" act as described? Two platina points project one-sixteenth of an inch through a canula; the platina wires are insulated to near the points; the opposite ends are connected to positive and negative pole of a battery; the circuit is to be completed by projecting the platina points against a bullet imbedded in the tissues of the human body.

This would no doubt work admirably, were the experiment tried outside of the body. But a line of contusion in the body, made by the passage of a metallic projectile will be filled with moisture, and the instant the probe point enters it, the moisture surrounding the platina points will complete the electric circuit as readily as if you had plunged the point into a tumbler of water.

Water is a fair conductor of electricity, and its conducting power is increased when it contains chloride of sodium in solution. The latter is present in the contents of sinuses through which we are most likely to wish to pass such a probe for diagnostic purposes. I therefore claim that such an invention, though in theory correct, is in practice unavailable.

Yours truly,
J. H. Payne, M. D.

Julietta, Ind.,
Oct. 3, 1889.

[Dr. Payne's criticism is incorrect. The whole basis of the invention, as properly described by Dr. Bashore, is "the greater conductivity of metal compared with the surrounding tissues of the body." There is some current all the time, of course, but the telephone or magnet only indicates the greater current produced in the circuit when it is closed by a bullet or other piece of metal. The small battery makes this possible.—Editor of the Reporter.]

New Hypodermic Syringe.

To the Editor.

Sir: I notice in the Reporter, Sept. 28, an article by John J. Thomas, M. D., of Youngstown, Ohio, in regard to a new form of hypodermic syringe. I think it has one fault, and that a very important one—the impossibility of total exclusion of air. The

suction of the bulb itself will not always do it; neither will the pressure of the thumb and finger always graduate finely enough.

Yours truly,

W. H. Lewis, M. D.

Birnamwood, Wis.,
Oct. 6, 1889.

Notes and Comments.

The Venom of Snakes.

The venom of the rattlesnake has been frequently made the subject of study, and, while its action as a poison has been generally conceded, some writers have endeavored to prove its efficacy as a drug. Surgeon L. A. Waddell, M. B., has recently been availing himself of his opportunities as a deputy sanitary commissioner in Bengal to determine a point about which it would seem that much uncertainty existed—the curious question of the effect of serpent venom on the serpents themselves. In a paper he has published he quotes the contradictory conclusions arrived at by previous experimenters, and endeavors to show that, from the accounts of the experiments, it by no means followed that death, when it occurred, was the result of auto-toxic action. Accordingly, he felt that the question was still open, and proceeded to some very interesting investigations, conducted under different conditions of temperature and season, verifying his results by control experiments upon other animals and by *post-mortem* examination of the snakes he employed. In every case the fresh venom was injected into the cobra with an ordinary hypodermic syringe; the serpents operated upon were all healthy, and had recently been caught; the snakes were kept under observation from nine to fifteen days subsequently, and were then killed. The experiments generally confirm and extend the principle formulated by Fontana in 1765, that the venom is neither a poison to the snake itself nor to those of its own species. This immunity is not to be explained upon the mere fact of the animal being cold-blooded, or upon the anatomical conformation of ophidians, since most, if not all, of the non-venomous snakes are susceptible to venom. Surgeon Waddell suggests that it may result from a toleration established through frequent imbibition of the venom in the modified or attenuated form which it assumes when mixed with salivary and gastric juices and absorbed through the alimentary canal, and in support of this hypothesis he mentions the popular belief that certain snake-charmers, by a process of inoculation with venom, gain protection against the bite of a particular species of venomous snake. If this hypothesis can be verified by further experiments, it will go far towards affording indications for combating the action of the venom on man. The subject is of such importance, and the experiments detailed appear so conclusive, that we look forward with interest to the further prosecution of this inquiry.—*Lancet*, June 15, 1889.

Leprosy as Observed in England.

In the *British Medical Journal*, June 29, 1889, Dr. Jonathan Hutchinson says that it is generally believed that the profession divides itself into two camps, one asserting contagion and the other denying it. Now the truth is probably nearly this. No one denies the possibility of contagion in what may be called the abstract or non-practical sense, while all, or very nearly all, doubt whether contagion takes any important share in the spread of the disease. A recent experiment by inoculation appears to have proved that contagion can be artificially effected, but it does not prove, and is far from making probable, that accidental contagion is common or easy. With due care in the transplantation of a bit of living tissue, no doubt lupus might be transferred from one person to another and so also cancer, but neither of these diseases is contagious in a practical sense. In neither is there any necessity for isolation of the sufferer in order to give safety to others. Those who believe in the importance of the bacillus as being perhaps the *vera causa* of leprosy are bound also to believe that the disease may be contagious. The practical question is, however, under what conditions does it become so. On this point the testimony of modern observers in leprosy districts is very nearly unanimous. Neither in Norway, in Hindustan, or the West Indian Islands, do nurses or surgeons fear to come in contact with lepers from day to day for years together. So far as contagion is concerned, hundreds of surgeons, well acquainted with the dreadful nature of the disease, daily encounter the same risks that Father Damien did. They do so, however, in the firm conviction that the risk is nothing.

The sad illness and death of the hero-priest has impressed the public with the belief that the disease is contagious, whereas it proves no such thing. The risks to which he exposed himself were far other than those of contagion—they were those of food as well. When I visited the leper establishments in Norway some years ago, I made diligent inquiry for instances of apparent contagion; I asked more especially whether strangers visiting Norway ever contracted it. Everywhere I met with an emphatic negative, but everywhere I was told of one well-known exception. This exception was a certain German officer who had come to live in Norway and had become a leper; but, added my informants, "he degraded himself and lived amongst the fishermen as they did, and he deserved to get it." The large leper establishments at Bergen and Molde were officered by healthy persons, and no one feared the disease. Recent microscopic discoveries have done something to explain the difficulty of contagion while at the same time confirming our belief in its possibility. They have shown that the microbe, which is no doubt the means of contagion, flourishes only in the true skin, and never invades the epidermis; and, further, that it is not present in the granulations of ulcerated parts. Thus it can probably be transferred only when special care is taken to secure the success of the experiment.

Our experience as to lepers in England is all in the strongest possible sense adverse to the belief in accidental contagion. We admit them into our hospitals, and observe no precautions; we allow them to mix freely with their relatives; in the case of children, to go to school; and, to give lastly the strongest possible proof, we permit leprous husbands to continue cohabitation with their unaffected wives, and no ill results ensue. I have with my present knowledge at least three married couples living under the conditions suggested, and in no instance has the wife suffered. Indeed, to sum up, there has not been in England, within my knowledge, a single instance of even suspected contagion. I have never myself seen a single patient in whom the disease had not been acquired during residence abroad.

The facts to which reference has been made being generally admitted, and once for all considered as beyond debate, the problem before us in our search for a cause becomes I think much narrowed. We feel sure that this cause is not contagion, we feel sure that there is nothing in even the slightest degree associated with poverty, dirt, or hardship, we feel sure that nothing that we know of under the name of climate has anything to do with it. What then have we left us to inquire about? Little or nothing I would submit excepting the all-important question of food. Since it can begin without inheritance, is with the utmost difficulty contagious, since it effects those who live in hot climates, just as it does those who live in cold ones, pays no respect to wealth and station, to age or sex, but of those who live in the districts and conform to the local modes of life picks out one here and another there, we are I think driven to the conclusion that it must depend upon some very special kind of poison of rare occurrence taken in connection with food. Such an hypothesis would cover all the facts, and none other would. I do not believe that it is possible to suggest any other that would not be instantly confuted by the facts. If we conceive that the bacillus is received into the body in some article of food, and add to our hypothesis that it is probably by no means commonly present, we see at once how the occasional but very rare infection of those who visit leprous districts may be brought about, and how it is that of the natives themselves only a minority suffer. We see also how it is that recoveries now and then occur in those who leave the dangerous districts, whilst they are seldom or never witnessed in those who remain.

If the hypothesis here explained be the correct one, the kind of investigation now required is evident. We know enough as to the clinical history of leprosy and as to its pathological anatomy. We accept the bacillus as, in some sense at least, its cause, and we now have to seek the spores of the bacillus in the foods employed in the districts in which it is prevalent. This will doubtless be a difficult and laborious matter, but by judicious collection of facts I do not doubt that the scope of the inquiry may be narrowed to one of much smaller compass. We have to find some kind of food which is used in all the districts in which the disease prevails, and which is either wholly or partially disused in those where it is not known. We have to ask in what directions the progress of European civilization has modified the dietetic habits of the communities.

Dr. Hutchinson then cites a case of leprosy under his care which proves first, that leprosy

may be acquired without inheritance, by residence in a district where it is endemic; secondly, that it is not necessary that there should be any exposure to hardship or poor food; thirdly, and most importantly, that the leprosy process may come entirely to an end during residence in England; fourthly, as regards the food hypothesis, we have the fact that the patient had eaten fish freely in Jamaica, almost every day, and that she abstained from it in England.

Diagnosis of Disease of the Pancreas.

From careful examination of a case which was under Gerhardt's care at the Berlin Charité, van Ackeren endeavors to assign a certain diagnostic importance to the presence of undecomposed carbo-hydrates in the urine of cases suffering from disease of the pancreas. The patient was a man, 49 years of age, admitted suffering from vomiting, constipation, and emaciation. To the right of the umbilicus there was palpable a painful irregular tumor which moved to the right when the stomach was full. The emaciation progressed, although the size of the tumor scarcely increased; œdema of the legs and ultimately ascites and hydrothorax set in, and he died five months after admission. At the necropsy there was found in the pyloric region an ulcerated carcinoma with secondary growths in the retro-peritoneal glands. Two such nodes were present in the pancreas—one in the tail and a larger one in the head of the gland. Two or three weeks before death, the urine, which had hitherto been normal, increased in quantity, notwithstanding the œdema, and the specific gravity went up to 1028 and 1030. Fehling's solution showed reduction only some time after heating, while the nitrate of bismuth solution turned black after some minutes' boiling. Polarized light was rotated to the right, and the fermentation test gave a positive result. The application of other tests showed these reactions as due to the presence of maltose and a closely allied carbohydrate. Indican was present in abundance, and there was no biliary pigment. The motions, although repeatedly examined, never showed any fat, but, on the other hand, there were numerous striped muscular fibres. As these symptoms were added to those of cancer of the stomach only two or three weeks before death, they probably coincided with the occurrence of secondary growths in the pancreas. The presence of striped muscular fibres in the feces was of great importance, as they have been found in nearly all those cases, although here, as shown by the constipation which existed, they could not be looked upon as due to a rapid passage through the intestine. Both this symptom and the absence of indican from the urine have been attributed to the failure of trypsin. In a case recorded by Gerhardt, in which the enlarged head of the pancreas had led to intestinal obstruction, indican was absent, and that observer sought to invest it with some diagnostic significance; but it may be explained by albuminous matter not entering the intestine, as it has been shown that indican disappears entirely by the third day in cases of inanition. In this case it was present in abundance. With regard to the presence of fat in the feces, F. Müller has shown that when this occurs the case is always complicated by other conditions, especially jaundice. Here no biliary pigment appeared in the urine, nor was there any fat in the motions. According to von Mering, the pancreas possesses the most powerful diastatic ferment; and it is probable that it is the pancreatic secretion alone which converts the maltose, derived from the carbohydrates of the food, into grape sugar. As carbohydrates do not appear in the motions, the only symptom pointing to disturbance of this process is the excretion of sugar in the urine, and in this connection it is interesting to recall the fact, long ago observed by Frerichs, that in diabetes mellitus the pancreas is frequently found much atrophied.—*Practitioner*, June, 1889.

How Drunkards are Treated in Norway.

The London correspondent of the *American Practitioner and News* says that a well-known medical man, who has recently been in Norway, gives a glowing description of their manner of treating dipsomaniacs. An habitual drunkard in Sweden and Norway is treated as a criminal in this sense, that his inordinate love of strong drink renders him liable to imprisonment, and while in confinement it appears he is cured of his bad propensities on a plan which, though simple enough, is said to produce marvelous effects. From the day the confirmed drunkard is incarcerated, no nourishment is served to him or her but bread and wine. The bread, however, it should be said, cannot be eaten

apart from the wine, but is steeped in a bowl of it and left to soak thus an hour or more before the meal is served to the delinquent. The first day the habitual toper takes his food in this shape without the slightest repugnance; the second day he finds it less agreeable to his palate, and very quickly he evinces a positive aversion to it. Generally, the doctor states, eight or ten days of this regimen is more than sufficient to make a man loathe the very sight of wine, and even refuse the prison dish set before him. This manner of curing drunken habits is said to succeed almost without exception, and men or women who have undergone the treatment not only rarely return to their evil ways, but from sheer disgust they frequently become total abstainers afterward. —*Northwestern Lancet*, July 1, 1889.

Adonis Vernalis in Heart Disease.

L. Jumon states in *La France Médicale*, March 12, 1889, that *Adonis vernalis* has been employed in Russia from time immemorial as a domestic remedy in diseases of the heart, dropsy, etc. For some years it has been frequently the object of scientific investigation. Adonidin and picro-adonidin have been isolated from it; the latter has been employed with good result in cases of mitral and aortic insufficiency. It is given in chloroform water, in doses of one-sixty-fourth of a grain daily. In Italy another species of this plant, *Adonis æstivalis*, grows. Experiments instituted with it by Marfori and Borgiotti show an important improvement of the subjective symptoms of patients: cyanosis disappeared, diuresis occurred, œdema quickly subsided, digestion improved and the appetite returned. In some cases contraction of the volume of the heart and of the liver and dilatation of the pupil were observed. The frequency of the heart beat diminished with the increase of the dimesis. Special indications for adonis are: heart affections accompanied with pronounced symptoms of blood stasis; in these cases adonis brings about both a regular rhythm and also a diuresis lasting some time. The remedy is to be preferred to digitalis in that it can be employed without interruption until complete recovery occurs—for about fifteen to twenty consecutive days, so that diuresis becomes normal. The dose is from sixty to one hundred and twenty grains in the form of an infusion.—*Deutsche Medizinal-Zeitung*, June 20, 1889.

Preparing and Mounting Sections of Brain.

The method which we have found to give the best results in preparing, staining, and mounting sections of brain and spinal cord is that of Sigismund Freund, of the General Hospital, at Vienna. We gave it in the *National Druggist* several years ago, but repeat it now in answer to a request from a correspondent. It is as follows: "The material is to be hardened first in a solution of bichromate of potash, or in Erlich's fluid (bichromate of potash, 5 parts; sulphate of copper, 1 part; distilled water, 200 parts), and afterward in alcohol. The sections are floated in distilled water, and washed thoroughly. A staining fluid is made by mixing equal parts of a 1-per-cent. solution of chloride of gold in distilled water and strong alcohol. The washed sections are put in this and allowed to remain from three to five hours. From this stain they are removed to a fixing solution consisting of caustic potash, 1 part; distilled water, 5 or 6 parts, and allowed to remain in it for two or three minutes. From this solution they are removed directly to a 10-per-cent. solution of iodide of potash, where they immediately assume a rose color, which, in the course of a few minutes, deepens into red. At this point, if the sections are from adult tissues, the preparatory stage ceases, and they may be transferred to alcohol and mounted in the usual way, but the brain and spinal cord of an embryo are far too delicate to be handled in this way, and the author treats them as follows: The preparations are brought upon a glass slide, spread by means of a camel's-hair brush, and gently dried by covering (without pressure) with a piece of filtering paper. If the sections be very thin and soft, even this must be avoided, for the fibres of the paper would leave traces on the surface of the sections, and render them unfit for the study of the nervous elements. Nothing else can be done but to apply a piece of filter paper to the edges of the stained preparation lying on the slide, and to draw off the alkaline fluid in this way. This is by far the most tedious stage of the process, yet it is always possible to avoid shrinking and to preserve the most sensitive preparations. The sections, nearly dried, are allowed to remain in water a few

minutes and are then transferred to alcohol, and mounted in the usual manner in Canada balsam.—*National Druggist*, July 1, 1889.

American Academy of Medicine.

The American Academy of Medicine is endeavoring to make as complete a list as possible of the Alumni of Literary Colleges, in the United States and Canada, who have received the degree of M. D. All recipients of both degrees, literary and medical, are requested to forward their names, at once, to Dr. R. J. Dunglison, Secretary, 814 N. 16th street, Philadelphia, Pa.

Typhoid Bacilli in Drinking-Water.

The *Deutsche med. Wochenschrift*, July 4, 1889, states that in a certain part of a bathing village of Baden several cases of typhoid fever occurred in 1888. It was then learned that three of the persons who were taken sick in December drew their drinking-water from the same spring. In order to examine the water for bacteria, a flask holding about six fluid ounces provided with a ground-glass stopper, was rinsed out with a one per cent. solution of corrosive sublimate, and then sealed air tight with a rubber cap. The cap was removed at the spring, the water pumped for five minutes and every trace of corrosive sublimate removed from the flask and stopper. The bottle was then filled with the suspected spring-water and sealed with the stopper and rubber cap. Plate cultures made from the water showed after three days, on the average, 140,000 colonies for each cubic centimeter. A few colonies of typhoid bacilli developed on tin plates. These bacilli grew upon potatoes and showed the so-called polar granules. Hitherto typhoid bacilli in drinking-water have been certainly demonstrated only rarely.

A correspondent from Budapest writes to the *Wiener med. Presse*, August 18, 1889, that typhoid fever, which has been epidemic in different parts of the country, has broken out afresh, after a short pause, in the capital. Those regions, he says, are especially effected which are supplied with bad drinking-water, and whose newly completed streets and buildings have in them piles of filth and rubbish. One hundred and five cases of typhoid fever were brought to the notice of physicians in the first week in August.

NEWS.

—Dr. L. Brewer Hall has removed to 161 North 15th street, Philadelphia.

—Dr. Andrew Graydon has removed to 1338 Walnut street, Philadelphia.

—Dr. John B. Deaver has removed to 120 South 18th street, Philadelphia.

—Dr. W. B. Madden was killed at Johnstown, Pa., October 9. He was run over by a train while trying to cross the track.

—It is alleged that trichinæ have been discovered in hogs imported from the United States in San Louis Potosi, Mexico.

—The opening exercises of the Training School for Nurses of the Johns Hopkins Hospital, Baltimore, were held October 9, 1889.

—The remains of three more victims of the Johnstown flood were taken from Stony creek October 9. They could not be identified.

—Dr. F. L. Bowden, ex-Chairman of the Republican State Committee of Massachusetts, was stricken with paralysis at his home, in North Attleboro, on October 9.

—The President of the State Board of Health of Florida reports several cases of yellow fever at Key West. Precautions have been taken to prevent the spread of the disease.

—A Dr. Hugh M. Sutherland died from the effect of morphine poisoning at Bellevue Hospital, New York, October 10. He was but 29 years of age. His habits of dissipation, to which his suicide is chargeable, drove his wife to self-murder, her suicide occurring some time ago.

—Typhoid fever is epidemic at Aurora, W. Va., and it is said the country for miles around is infected. It is said that there is scarcely a family without one or more of its members prostrated with the disease, and in some localities there are scarcely enough well persons to nurse the sick.

—The first of the Philadelphia Polyclinic Evening Lectures, for the season of 1889 and 1890, was given October 8, 1889, by Dr. B. Alexander Randall. His subject was "The Anatomy of the Labyrinth of the Ear." The course is free to members of the profession and to medical students.

—Great excitement was caused in the beginning of October by the sending of poisoned candy to several clergymen in St.

John, N. B. The wife of one of the clergymen died after eating some of the candy, which contained strychnine. On investigation it is believed that the culprit is a man who had been in an Asylum but had been discharged as cured in May last.

—In Michigan, the reports to the State Board of Health for the week ending October 5, 1889, indicate that tonsilitis, typho-malarial fever, influenza, erysipelas, scarlet fever, puerperal fever and membranous croup had increased, and that cholera infantum, inflammation of the bowels, cerebro-spinal meningitis, inflammation of the brain and measles had decreased in area of prevalence.

—The charge of cruelty to an inmate against the Friends' Asylum, in Philadelphia, referred to in the REPORTER, October 5, have been investigated by the State Committee on Lunacy and it reports that "After taking the testimony of said complainants and of such witnesses as were on notice produced, we are unanimously of the opinion that the complaints are not well sustained, and that there has been no evidence produced which should impair the confidence of the public in this institution."

—The Bulletins heretofore issued by the Secretary of the State Board of Health of Michigan have mentioned the increase or decrease of diseases in which a difference of seven or more was shown between the percentage of reports stating the presence of the disease in the current week or month and in the preceding week or month, or in the corresponding month in previous years. Hereafter those diseases will be mentioned of which the comparison shows an increase or decrease of twenty-five per cent. from the preceding week or month, or from the normal, as the case may be.

—A preliminary injunction was granted October 8 against Dr. John L. Seitz restraining him from the practice of medicine in Harrisburg, Pa. The writ was asked for by Dr. Frost, who claimed he purchased Dr. Seitz's practice and was introduced by that gentleman among his friends as his successor. In the agreement Dr. Seitz was not to return to Harrisburg to practice his profession after he left for Columbus, Ohio. He returned, however, and resumed the practice of medicine in August. Argument will be heard October 14, when the Court will be asked to continue the preliminary injunction. Both are well-known physicians.

HUMOR.

DOCTORS WHO CAN SPEAK only one language seem to understand a great many different tongues.

HOLDING ON.—The story comes from the West of a miser who swallowed a five-dollar gold piece, but the stomach-pump could only bring up $4.50.

QUEER PROOF-CORRECTING.—Some very amusing ways of marking mistakes in a proof are used by outside proof-readers, especially clergymen. A minister, in reading a proof of his sermon, discovered a "space" that was not shoved down. The space, of course, made a black mark, and instead of making an x on the margin, which is the regulation mark, he wrote the following: "To the compositor:—☞Please remove the superfluous mark before the word Paradise in this line." Another, wishing to have a letter turned rightside up, sent these instructions to the compositor: "Please insert an e that is not reversed." Another, finding a word that he thought spelled wrong, wrote the following on the margin of the proof-sheet: "The word with the line drawn through it don't look exactly right; consult your dictionary, and oblige." This way of marking proof is not relished by compositors, and does not tend to better their religious instructions.

PATRONIZING YOUNG DOCTOR.—There is a story going about so good that it ought to be made public, and so improbable that it must be true. A very eminent London surgeon—one of the lights of the profession—the other day observed a gentleman fall in the street. He went to his aid, and found he had broken his leg. It was only a simple fracture, but the man was badly hurt. The surgeon used his umbrella as a splint, and, with his own and borrowed handkerchiefs, bandaged the limb tightly, put the patient in a cab and drove to the nearest hospital. There they were received by a young surgeon or his locum tenens. "You've bandaged this very well," said the hospital surgeon. "You flatter me," said the great surgeon. "Not at all," said the other. "I suppose you've been attending an ambulance class. They say a little learning is a dangerous thing, but the little you've learnt you've put to good account. I can't give you your umbrella now, but if you leave your address it shall be sent home." "I had best give you my card," said the eminent surgeon. And he did so.

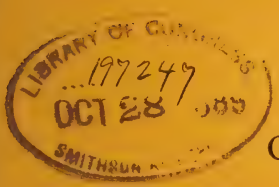
A WEEKLY JOURNAL



CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER,
N. E. COR. 13th & WALNUT STS., PHILADELPHIA.

ENTERED AS SECOND-CLASS MAIL MATTER AT PHILADELPHIA P. O.

WE OFFER

"PEPTOGENIC MILK POWDER"

as a means of modifying cows' milk quantitatively and qualitatively to the ascertained composition of normal mothers' milk.

Cows' milk with this Powder and the directions given yields a "humanized milk" which in chemical constitution, physical character and taste approaches very closely to human milk.

"PEPTOGENIC MILK POWDER" is designed for the sole purpose of preparing from cows' milk an adequate substitute for breast milk. It has been prepared upon the basis of comparative analyses of cows' and human milk, and its prime pivotal factor is the transformation of the caseine and other albuminoids by a digestive ferment into a form in which they remarkably agree with those designed by nature for the food of an infant.

This being accomplished, there remains no necessity for the intervention of any inert or foreign substance, or of the crude expedients hitherto employed in the attempt to overcome the inherent unfitness of cows' milk as a substitute for mothers' milk.

We do not, under any circumstances, offer "PEPTOGENIC MILK POWDER" as a Food. We do not manufacture an Infant Food.

We offer a means and a method by which a mother may, from cows' milk, cream and water, prepare a physiological substitute for breast milk.

FAIRCHILD BROS. & FOSTER,
82 & 84 FULTON STREET,
NEW YORK.

EVERY PHYSICIAN

prescribing Cod Liver Oil (and who does not?) wants to know that his patients get the best that can be obtained. This is effectually secured by specifying **" BAKER'S "** whose firm (established in 1830) have given the greatest attention to the improvement and perfection of this all important remedy. In the various conditions in which Oleum Morrhuæ is indicated the Practitioner must decide the best form of administration. To meet such conditions we offer:

BAKER'S COD LIVER OIL.

BAKER'S EMULSION WITH HYPOPHOSPHITES OF LIME AND SODA.

Baker's C. L. Oil with Ext. of Malt.

Baker's C. L. Oil, Lime and Wild Cherry.

Above goods are accessible through the wholesale trade to all Retailers, and may be prescribed with the utmost confidence as to Purity and Excellence.

JOHN C. BAKER & CO., PHILADELPHIA, PA.

Physicians and Students of Medicine

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders**, is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds**, handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe, and healthful Home.

ANTISEPTIC SURGERY—LUXATION OF ELBOW—DOUBLE HYDROCELE—DIABETIC GANGRENE.[1]

BY THOMAS G. MORTON, M. D.,

ONE OF THE VISITING SURGEONS.

Amputation of the Fore-Arm—First Dressing.

Gentlemen: This patient, a laborer, aged 25, was admitted on the 20th of September, sixteen days ago. His hand had been caught in some machinery and crushed. I saw the patient an hour after his admittance. He was suffering from slight shock. Upon examination the parts were found to be so hopelessly crushed that amputation was necessary. I made two flaps—an anterior and a posterior—of skin and a circular division of the muscles. The operation was conducted with strict antisepsis. A drain of cat-gut was introduced and sutures of the same material were used to close the wound. We have not dressed the arm since, now sixteen days. Formerly we were not able to do this, but were compelled to take off all dressings as a rule shortly after operations on account of suppuration. But all this has now changed because antiseptic dressings are at present always employed. By their use we secure immediate union of wounds. Since such wonderful effects have been attained by the use of antiseptics it is well occasionally to go over the subject of the modern scientific wound treatment.

A wound that heals by primary intention is one in which the edges are glued together by plastic lymph wherein healing is accomplished without suppuration. In wounds which do not so heal, we have suppuration with all its dangers, and healing is prolonged. In order to secure closing of a wound by primary intention we must prevent fermen-

[1] Delivered October 7 at the Pennsylvania Hospital.

tation or decomposition. Three conditions are necessary to produce putrefaction, these are moisture, warmth and living organism. Remove either one of these three conditions, and we prevent suppuration and putrefaction. If we remove moisture there cannot be decomposition; by the removal of warmth animal substance will not putrefy; by the exclusion of living organisms (bacteria) we can also control putrefaction. We accomplish the latter by means of germicides. Although moisture and warmth are present, germs are excluded or killed, and so fermentation is avoided. We cannot get rid of moisture or warmth, but we can exclude live germs. The antiseptic *dressing* is but the conclusion of a series of manipulations upon a part before, during and after an operation, and is about valueless unless all previous details of antisepsis are properly carried out.

I now show you the condition of the stump by removing the dressings. It is, as you see, perfectly well. The blood-vessels were tied with gut, the drain was also gut, both have been absorbed. Where the drain came out there is still a small unhealed spot. In using a foreign substance, as glass or rubber, for purposes of drainage it is necessary to remove the dressing early because these are foreign bodies. The gut, however, being an animal substance, is capable of absorption. All of our wound-washing is done with bichloride solutions. Unless we absolutely carry out the rules governing antisepsis we are not just to our patient. In this jar we have the mercuric solution which we allow to flow over the wound in the manner you now see. We place the protective (a piece of oiled silk treated with copal varnish and dextrin) over the wound, over this the antiseptic gauze and cotton and then apply the gauze bandage. The man may now go home.

Dislocation of Elbow.

This boy, aged 8, has just been admitted with a peculiar deformity of the elbow. He fell striking upon his palm. What is the nature of the injury? In the first place we have deformity. When we compare the two elbows we can observe this more clearly. It looks like a dislocation, but there may be a fracture, or both. There is an apparent widening of the condyles and there is an unnatural prominence posteriorly. The symptoms of fracture are pain, deformity and crepitus. I do not discover crepitation. To establish the diagnosis we take the hand of the injured side and also grasp his elbow and ascertain if the forearm is involved. Making pronation and supination we discover a normal condition of the radius. Force applied to the ulna may, in driving it against the humerus, produce splitting of the condyles. Upon examination of this case, however, I find it to be an uncomplicated dislocation of the elbow; a very unusual accident in so young a person. We give him ether, which is always a prudent measure to accurately determine the nature of such an injury. There is no dislocation more important to reduce at once than luxation at the elbow. An unreduced elbow luxation is very difficult to overcome after two or three weeks. In securing reduction hold the humerus firmly, draw the forearm backward, and, at the same time, make flexion. Probably some of you heard the ulna slip into place. We apply a bandage and direct the boy not to use his arm for a couple of weeks.

Double Hydrocele.

The case I show you now is one of hydrocele, an exceedingly common affection. When we speak of hydrocele, we usually speak of it as occurring in the male, but it may occur in analogous parts of the female. It consists of an accumulation of fluid in the tunica-vaginalis. It may be single or double. As seen in the scrotum, it appears as a tumor, pyriform in shape. The amount of fluid may vary from a few drachms to a gallon or more, the tumor reaching down to the knee.

The diagnosis of hydrocele is very simple. In the first place we make our diagnosis by means of the light transmitted through the tumor from a candle in a dark room. Having a pyriform tumor, with the history of a slight injury, and the transmission of light, we may positively conclude that a hydrocele is present. We exclude the existence of hernia by grasping the base of the tumor and asking the patient to cough, when, if no impulse is felt, hernia may be excluded.

There are several forms of treatment. The palliative consists in drawing off the fluid by means of the trochar. The patient, however, after being tapped two or three times, usually desires a radical operation. This may consist in the opening and draining of the tunica-vaginalis; or of dissecting out the sac. The old method consists of the injection of some irritating substance. Formerly surgeons used red wine, to-day we

employ tincture of iodine. The trochar is entered on the anterior surface of the tumor to avoid the testicle. This sac is so very tough and thick that the trochar will not penetrate, and instead of injecting iodine, I will incise the tunica-vaginilis, remove a portion of it, insert a cat-gut drain, and expect the cavity to be obliterated by universal adhesions.

The fluid of a hydrocele is generally a clear amber color, though it may at times be white like milk, especially in old people and in encysted hydroceles connected with the testicle substance, the color is then often due to the presence of spermatozoa. We must be careful that the hydrocele is not congenital (when a direct communication with the peritoneal cavity is often present); for, if so, the injecting fluid, should it gain access to that cavity, would produce peritonitis. Infantile hydrocele will often get well without interference.

I have now exposed the testicle, and you see that it is perfectly free from disease. We have a sac here which will hold four or five ounces. I trim out a portion of the tunica-vaginalis, and inserting a cat-gut drain, close the wound about it with three or four gut sutures. On the opposite side you notice that the tunic is unsually thick. I will remove a portion of it, and carry a similar drain well up in contact with the testicle.

Diabetic Gangrene.

This patient presents an unusual form of disease. It is a case of gangrene in a diabetic. Gangrene may arise from many causes, but there are probably none more interesting than that exemplified by this case. In diabetics, a very trivial injury, even so simple an operation as the cutting of a corn, is liable to produce this form of gangrene.

This patient a colored man, by occupation a caterer, aged 50, was admitted on the 24th of August with his present trouble. He is passing a large amount of a very pale urine with a high specific gravity, answering to the various tests for sugar. The gangrene now involves the third toe of the right foot, the second toe having been removed some time since for the same trouble. A very interesting paper was read by Dr. Hunt, a year ago, before one of our medical associations, in which he very thoroughly reviews this subject. In it he draws the distinction between diabetic and senile gangrene; to which latter as you know people of advanced years are very liable. It occurs in the extremities, is due to vascular changes, and presents a clear cut line of demarcation between diseased and healthy tissue, which line, Dr. Hunt says, is never present in the diabetic variety. As a rule cases of diabetic gangrene had better be left alone, for operation is often followed by fatal results. However, when the mass is putrified, and consequently very offensive, we may be obliged to operate. This is our object in the present case. With the knife and curette I remove all of the diseased tissues as you see. We will now insert a cat-gut drain and a few gut sutures, and then dress the wound with iodoform, and dressings saturated in the mercuric solution.

CHRONIC OVARITIS.—ANTEFLEXION WITH INSANITY.[1]

BY E. E. MONTGOMERY, M. D.,

VISITING OBSTETRICIAN TO THE PHILADELPHIA HOSPITAL.

Chronic Ovaritis.

A young woman, aged 19 years, some months ago had one ovary removed in this institution. At that time the removal of the other was advised, but the operator yielded to the urgent request of the patient that it should be preserved. She is now brought before you for the purpose of thorough examination, as she complains of severe and continuous pain on the opposite side.

As the patient complains of severe pain as soon as the region of the ovary is touched, and her abdominal muscles become so rigid that it is difficult or almost impossible to outline the ovary, I propose to place her under the influence of an anæsthetic. For such examinations, the bromide of ethyl is an excellent agent, as it acts quickly, and the patient rapidly recovers from its effects, with less frequent nausea and vomiting than with the more usual anæsthetics. The patient, however, declines to take an anæsthetic, and we will make no effort at further examination to-day; for the pain upon manipulation is so great that we are unable to determine the size of the remaining organ. (Patient removed.)

This patient is a prostitute, and I would not do an operation unless I felt assured that

[1] Delivered at the Philadelphia Hospital.

the pathological conditions were such as to account for the unpleasant symptoms from which she claims to suffer; for women of this class often desire the operation from improper motives. It should be remembered, however, that when the removal of the appendages upon one side is indicated as a sequel of gonorrhœa, experience has demonstrated that the remaining tube and ovary are likely soon to become the seat of disease, producing just as severe suffering as before and necessitating a second operation. In these cases the disease, more than likely, exists in the apparently healthy tube in a latent state, and the removal of the other gives it an opportunity for expression.

While the removal of the ovaries should be looked upon as a *dernier ressort*, it is time lost to temporize when the presence of pus and extensive inflammatory products can be demonstrated, and much suffering can be avoided by a timely operation. Pain in the region of the ovary, without demonstrable pathological alterations, should not be considered an indication for operation until all other means of treatment have been exhausted. A practical question to be considered is the circumstances of the patient. If she is poor and dependent upon her own exertions for her support, it is self-evident that we should not resort to the same plan of treatment as in a woman who is able to give her whole time to the care of her health. In such a case the operation, its results, and other methods of relief should be laid before the patient, giving her a chance to choose for herself what she will have done.

Anteflexion with Insanity.

The next patient I show you is a woman, aged 29 years. The family history is bad. The father died of phthisis and the mother suffered from asthma; she had five brothers and sisters who died early and a sister still living suffers with frequent convulsions. This patient began to menstruate at thirteen, at seventeen she was married, and eight and a half years ago she was in an insane asylum. She suffered from attacks of severe menorrhagia and at the same time bled profusely from the stomach and nose; pain in the head was intense, and she had dragging pain in the abdomen. She was subject to severe epileptiform attacks, in which tonic and clonic convulsions occurred without the tongue's being bitten. Previous to, and during menstruation, pain was augmented.

On examination now, I find the uterus anteflexed. In examining a patient I advise that the rectal touch should be practiced as a part of the routine, not only when the uterus, but also when the ovaries are suspected to be the seat of the disease. Such an examination, taken together with the history previously obtained, will enable us in the majority of cases to arrive at a correct diagnosis of the condition. In cases of doubt, however, it is not wise to prematurely commit one's self. In some conditions, indeed, it may be necessary to arrive at a diagnosis, or at least confirm it, through treatment.

While upon the subject of examination, I cannot do better than to indicate a line of procedure. First, secure the family and personal history. This of itself will often reveal the probable condition. At the same time the close observer has noticed the indices of disease as written upon the face and form. As a second step, inspect the external genitalia. This should be the rule in every first examination. It is indicated from grounds of personal safety, as the patient may be infested with pubic pediculi or infected with some venereal disorder; it is indicated as affording valuable information as to the character and amount of discharge; the seat of bleeding—from granular vagina or vulva; the presence of caruncle or vascular urethra, hypertrophy of labia, lacerations or fissures of the vulvar orifice, and relaxed or prolapsed vagina.

By the touch we discover thickening, contraction and relaxation of the walls of the vagina; granular condition of its mucous membrane; absence of its rugæ; the presence or absence of its discharge, and prolapsus of the uterus or vaginal surfaces.

We should carefully observe the shape, size, lacerations and fissures of the os; the presence of granulations, erosions, abrasions, or cystic degeneration of its mucous membrane; the fixation or mobility of the uterus, and the presence of fecal accumulation in the rectum. With two fingers in the vagina, and the hand over the abdomen, the bimanual touch affords additional facility in investigating the condition of the pelvic organs, the shape, outline and position of the uterus and its appendages; its relations to surrounding organs or abnormal growths. The retro-uterine structures, the ovaries and tubes are more effectually examined by the recto-abdominal touch. The character and seat of pain experienced should be noted.

The symptoms in the case before us present evidence of disease of the pelvic viscera. There is hyperemia in which menstruation is frequent, and in which there is much pain in the intervals and particularly just before the advent of the menstrual flow. We find here, as in all such cases, a strong tendency to anemia. It is a well-observed fact that the hyperemia of the uterus and the general anemia act and react upon each other. Sterility is another frequent symptom, although it may also result from disease of the appendages as well—a condition which our examination has disclosed here exists.

The dysmenorrhœa, however, should be considered as due to the uterine rather than the ovarian disease. In the latter form the severe pain is felt for a week or ten days before the flow, while the menstrual flow gives relief. Here the pain is felt just before and during menstruation, while the function is followed by the epileptiform attacks which will further break down her health.

The treatment is constitutional and local. The former consists in the adoption of such measures and the administration of such remedies as will best promote the general nutrition. To best accomplish this it is necessary to study the patient's history. We find her holding an inheritance of insanity and consumption. Her nervous system and general hygiene are first to be considered. The mental development of a person with neurasthenic tendencies should not be forced, especially during that period in which the sexual apparatus is making its most rapid development. Childhood should be prolonged, education and accomplishments deferred. Ample rest should be secured and during the menstrual periods, for the first year, it would be well to confine the patient to bed. The imagination should be restrained rather than cultivated. All reading that appeals strongly to the emotions should be avoided.

Although too late to correct the errors of developmental changes, much may be done by securing proper rest, sound sleep and suitable diversion to ameliorate the unpleasant symptoms. In this patient we have an additional trouble in that there is an hereditary predisposition to phthisis. What has been said of the reconstructive power of mental rest and recreation is no less applicable to the physical treatment of phthisis. Judicious exercise, pleasant and healthful surroundings and rest are the three great hygienic requirements for the prevention or the cure of this disease, and the stronger the predisposition, the more firmly their observance should be demanded.

The remedies that will be found most valuable are cod liver oil, iron, arsenic, phosphorus and strychnine.

The local treatment will consist in replacing and overcoming the anteflexion. You will find many methods of procedure suggested. Thus, dilatation of the cervix is said to straighten the canal, and the laceration of some of its fibres to cause an exudation of plastic lymph into the walls, which serves as a splint to keep the organ straight. This, however, is not always true. Relief not only does not always follow, but when it does, it is usually only temporary.

Lateral dilatation is most frequently done, although it is questionable whether the antero-posterior dilatation of Schultze is not preferable. Molesworth's circular dilatation, followed by the use of bougies, is, in my opinion, the choice procedure; but it is necessary the latter should be frequently repeated to prevent contraction. Many cases will be greatly improved by a stem pessary, of either glass or vulcanite. This instrument straightens the canal, keeps the inflamed surfaces separated, and promotes the uterine circulation.

The use of a Faradic current, through a bipolar electrode, is frequently of great benefit, promoting the nutrition of the muscular walls and increasing the tonicity of the blood-vessels. Where all the methods above suggested have failed, where the recurring menstrual distress is sufficient to induce severe mental disturbance I have no hesitancy in recommending the sacrifice of the appendages.

—Handling Thin Animal Sections.—Those who are accustomed to handling vegetable sections must remember when they come to work with animal specimens that the latter are much more liable to break or tear than vegetable sections. If this is not borne in mind valuable specimens will be ruined while handling them.

—It is stated that the kangaroo is in danger of being extinguished. Its skin is so valuable, says *Nature*, that large numbers of young kangaroos are killed; and authorities are of opinion, that, unless the process is stopped, Australians will soon have seen the last specimen of this interesting animal.

COMMUNICATIONS.

HEMATOMETRA.[1]

BY FERDINAND H. GROSS, M. D.,
PHILADELPHIA.

In the experience of most of us, hematometra is of infrequent occurrence. This rareness, and not that I have anything new to say on the subject, is my chief inducement for reporting to the Society with some detail, two cases of this hematic tumor, which came under my observation in the early months of the current year; indeed, the case to be presently mentioned, afforded me the first opportunity in a good many years of experience as a practitioner, of estimating clearly the importance of the condition. But in the lapse of only a few weeks, a second case presented itself for my treatment. Atresia of the vagina I had repeatedly observed, but never its contingent, hematometra. In the cases to which allusion has just been made, the atresia existed, in one at the lower end of the vaginal tube, while in the other it consisted in an obliteration of the cervical canal of the uterus; and thus were exemplified two interesting varieties of the occlusion.

A young girl who had been under the care of different physicians, without the source of her troubles being fully recognized, was referred to me by a medical friend for treatment, with the information that a tumor occupied the vagina and filled up the lower pelvis.

The patient was in her fourteenth year, and therefore at the age of puberty; but she had never menstruated—that is to say, no visible signs of the catamenial flow had been noticed. The first disturbances of her health had occurred about six months before, and although she never felt quite well afterward, her indisposition for a time caused no apprehension. But a number of subsequent paroxysms of augmented severity attracted anxious attention. In short, the alarming character of the exacerbations led to a physician being consulted.

When later on, in an advanced stage, the case was referred to me, a digital examination of the vulva revealed protruding therefrom a smooth and very tense swelling, in which the experienced touch could readily detect fluctuation, a feature of the mass very clearly evinced by the rectal exploration. Neither the examining finger nor the probe could find anywhere between this protrusion and the labia an entrance to the vagina. The hypogastrium had become prominent from a tumefaction which arose from the pelvis. This enlargement in the course of its development had been noticed to be most sensitive during the paroxysmal attacks, which were doubtless the regular menstrual molimina. The continuous abnormal pressure upon the pelvic organs was the occasion of vesical and rectal tenesmus as well as obstipation; and restless nights were the inseparable accompaniments of such torments. But aside from these there were symptoms of a subjective character, such as headache, giddiness, nausea, and other gastric distress, a feeling of painful fulness in the abdomen, palpitation, and disturbed vision which the prescribed glasses of the oculist had failed to relieve. This complex of distressing and long-enduring symptoms was sufficiently pointing to lead to the diagnosis of hematometra as a contingent upon atresia hymenalis.

It is not my purpose here to recount with exhaustive minuteness the various results of hematometra, if relief be not given in good time by what is usually a simple surgical expedient. Nor would the time allotted permit me to speak of the lesion as it occurs in double vagina, in duplex uterus, and in other malformations of the female generative organs. Greulich relates in concise form, but with sufficient clearness, the different issues of this condition, and cites an array of authors who appear in the literature of the subject. But some of the results of this blood-tumor should not remain unnoticed in this place. Much may depend upon the period of life at which the artesia has been acquired. For example, in the climateric age the hematometra may eventually be tolerated,[1] or at least borne with less suffering or discomfort, since at this period of change the tumor may cease to enlarge because of the discontinuance of the menstrual secretion. But also at periods prior to the menopause, the rapidity or slowness with which the uterine accumulation takes place, and consequently the degree of its evil effects upon the general organism, may depend

[1] Read at the Philadelphia County Medical Society, September 11, 1889.

[1] Real Encyclopædie der gesammten Heilkunde, vol. vi, page 180.

upon the character of the patient's constitution, whether this be plethoric and robust, or weakly and anemic. If the latter be the case, the increase of the pent-up menses may be very meagre or even nil; and again, if vicarious menstruation be established, the addition in utero would naturally be avoided, affording a degree of local relief, or at least checking for a time the progress of serious symptoms, provided the locality of the vicarious function be a safe one.

Among other possible results of this bloody accumulation are enumerated hematosalpinx, intraperitoneal hematocele, and hematoma of the ovarium, each with its serious consequences. But hematoma of the ovarium as well as effusion into the tube may occur by direct extravasation from congested vessels and yet hematometra be responsible for either occurrence, since hyperemia of the uterine appendages is one of the accompaniments or conditions of the hematic tumor we are considering. If, therefore, the already engorged plexuses or network of vessels of the environment be periodically subjected to additional blood-pressure, the bleeding that follows the bursting of a Graaffian follicle under normal circumstances may now become sufficiently copious to produce results of a pathological character.

Without stopping to speak of a possible rupture which would allow the secretions to flow off in a natural or harmless direction, adhesions may form with the neighboring hollow organs and perforation take place into bladder or rectum. Septicemia from decomposition within the womb is here the greatest danger. The entrance of urine on the one hand, or of fecal matter or intestinal gases on the other, would be favored by the womb's enfeebled contractile power, as that organ could not empty itself with promptness nor with that degree of force of which it is possessed when developed for a physiological purpose. The pressure of tumors is recognized as a cause of uterine atrophy and we can readily conceive in hematometra the attenuated condition of the muscular coat. Another danger of infection might be a vaginal cul-de-sac below the point of perforation into either of the hollow viscera mentioned, which would serve as a reservoir for decomposed matter.

Considering the possible results of this condition, no time was lost in providing for the escape of the accumulated secretions. Hymen imperforatum in a large majority of the cases is not discovered before the age of puberty, and the one referred to was doubtless of the congenital variety. The operation can hardly be called a painful one, but the girl had become so irritable and sensitive from long suffering and repeated examinations, that the puncture by trochar was made under ether narcosis. Thirty-two ounces of reddish-brown, chocolate-colored fluid was drawn off without interruption of flow. The canula being removed, a crucial incision with a probe-pointed bistoury enlarged the opening, whence a little fluid continued to ooze. Ergot was administered, but only gentle pressure was applied externally by an abdominal binder. The vagina was gently washed out with a weak solution of the bichloride. The uterus remained too high to be reached by the finger, and an examination per force was uncalled for. The vaginal surface was smooth and devoid of its rugæ. As an additional precaution, the pudendum was covered with compresses of antiseptic gauze.

It is to be remembered that the imperforate hymen is not a normal but a pathoanatomical structure. On the inner side its mucosa is continuous in cul-de-sac form with that of the vagina, and externally the mucous membrane is continuous with that of the vulva, while between these layers lies a fold of connective tissue. The membranous barrier in this case was found thick and tough beyond expectation, imparting the feel of soaked leather. The relief was prompt and decided; on the second day there was some pain in the hypogastrium, but no significant rise in the patient's temperature. In four weeks the menses were discharged in a normal manner, and this has recurred at regular intervals ever since.

In the second case alluded to, the woman is close upon forty years of age, and has lived in the marriage relation for half that period, but remains childless. The evidence she relates as pointing to a miscarriage in the third year of her married life, is not conclusive. After that time she enjoyed good health until thirteen years ago, when she "had a severe fall backward," after which she endured so much pain in trying to void her urine, that she fainted. Her physician said she had "dislocated her womb," and used instruments to replace it. She was confined to bed for three weeks and then treated in a hospital in this city; whence she returned home, still in a feeble condition, and remained in poor health for

several years. These early troubles are briefly mentioned since they concerned the genito-urinary organs, but I will not tax your patience with a history of subsequent maladies which had but doubtful or no connection with the patient's later complaint. Suffice it to say, that after an attack of typhoid fever as far back as 1883, she regained her former good health, and in all the years that followed until the month of May, 1888, the menstrual functions was regularly performed. It was then, however, that the lesion which concerns us here appears to have had its beginning. The monthly discharge of blood became scanty, and to the patient it appeared as though "a stringy leucorrhœal discharge had replaced the regular flow." Nor was she as free from pain as she had formerly been during her regular turns. In the following August her menses failed to appear, and the amenorrhœa continued for eight months; that is to say, until she was relieved by the operation to be mentioned further on. As regular as had been her monthly turns, just so regular were during those eight months the attacks of lumbar pains and uterine cramps, the severity of which increased with each returning molimen. In vain she now applied for relief both to regular and irregular practitioners. The latter advised her to enter their hospital and submit to a laparotomy for the removal of what they pronounced to be a "fibroid tumor attached to the uterus and left ovary." This advice was not followed, and it need hardly be said in this presence that the diagnosis was as incorrect as the laparotomy would have been unwarranted. The condition grew from bad to worse. From dire necessity the woman had learned to catheterize herself and was enabled by that means to get frequent relief from one of her greatest torments.

On the 30th of last March she entered the German Hospital, where she became my patient. On examination the next day, I found a large, smooth, very hard and firm tumefaction pressing low in the pelvis. The os could not be found and there was no discernible discharge from the vagina. Fluctuation was not at all perceptible, either by the vaginal or rectal examination. The mass had repeatedly been held by others to be a fibroid; but on hearing the patient's own account of the case, from which the above is a condensed statement, I declared it to be a hematometra, at once verified the diagnosis with an aspirator-needle, and on April 2 introduced an ordinary sized trochar to draw off the long pent-up secretions. In penetrating at the indistinct but supposed point of the former os, the instrument imparted the sensation of passing through a wall of considerable thickness before reaching the cavity, showing the obstruction to be something more than membranous. It was probably brought about by a stenosis of the inner os, combined with an endo-cevicitis and adhesions of the entire cervical canal.

The mahogany-colored, jelly-like fluid, or semi-fluid, could not flow freely through the canula of the trochar, but came only drop by drop. The cervix dilator therefore replaced the canula, and being used as a director for making a shallow crucial incision, a quart of the tarry substance was drawn off. The cavity of the womb was freely washed out with a continuous stream of the mercuric solution. Ether was not administered. The after-treatment was in the main similar to that instituted in the other case. Recovery was complete, and the patient has several times since the operation menstruated at regular periods.

SOME TENDENCIES OF MODERN MEDICATION.

BY JOSHUA W. READ, M. D.,
NEWARK, N, J.

A marked tendency of recent medication is in the direction of a continuous and limited administration of drugs. This has grown out of the now generally accepted idea, that the patient is the proper subject of treatment, rather than the disease with which he may be afflicted.

The notion that the doctor is simply a prescriber of medicines, and that his function wholly or in chief part ceases there, if it ever had a substantial basis either in theory or in practice, is rapidly disappearing before the advancing light of a more intelligent and successful conception of the practitioner's function. The disease as modified by constitutional diathesis, idiosyncrasies, sanitary surroundings, inherited conditions, and by many other influences which refuse to be classified, becomes a secondary consideration. Indeed, so clear are the indications, and for the most part so uniform the respective lines of medicinal treatment of the more important diseases, that it should become a mere routine matter

simple and relatively easy of execution, to prescribe the standard medicines for a simple unmodified case. But not so with the larger and broader function of treating the patient. As a practical matter, the doctor may often exercise his highest and best skill and accomplish the greatest possible good for his patient by advising the entire suspension of medication, as such. The day has already arrived when the intelligent physician is very wary about ascribing the recovery of his patient to the medicines employed. Thus far has skepticism in regard to the specific power of medicine over disease extended; and hence the tendency of to-day toward a limited and continuous medication.

Another manifest tendency of comparatively recent appearance, but which promises rapid development, is toward the exhibition of relatively small doses, frequently repeated. That an effect can be produced by this method of administration, not only different in character, but preferable in results, seems from our *present* standpoint, to say the least, highly probable.

It occurred to the writer to recently observe the most gratifying results from one-tenth grain doses of calomel repeated hourly until the desired effect was produced, in a case of obstinate constipation and general glandular inactivity, associated with the digestive disturbances of advanced Bright's disease. This peculiar pacific action of the remedy was realized much more promptly and satisfactorily, and with far less constitutional disturbance than would have been the case had the old-time single dose of ten grains been exhibited. The sentiment of the profession in favor of this method of medication seems to be rapidly gaining ground, as evidenced by the demand upon our manufacturing chemists for *granules*, *tablets*, *etc.*, containing minute doses. As an illustration we may mention what is well known to all, that tablets containing $\frac{1}{200}$ of a grain of corrosive sublimate are now kept in our leading pharmacies. Manifestly the tendency of the times is toward minutely divided doses; but, be it understood, this statement is not designed to convey the idea of infinitesimal dosage according to the homœopathic plan. Minute dosage is one thing and no dosage quite another.

The tendency of modern medication toward the employment of medicines easy and pleasant of administration has became so manifest and general in its application as to need but a bare allusion. Indeed, this tendency seems to have about reached the ultimate stage of realization!

This becomes apparent when we consider the all but universal employment of active principle, alkaloids, and concentrated medicines in general. It is hardly claimed that the therapeutical effects of remedies as a whole are improved by the use of their active principles. Indeed, I think there is ground for the fear that in some instances the active principle does not represent all that is valuable and desirable in the theuapeutical effect of the drug. However the tendency to a pleasant medication has become so imperative in its demands as to overcome some possible disadvantages, for it is a well-established therapeutical principle that all things else being equal the pleasant dose is much more likely to accomplish the desired result than the nauseous one, and *just here* we find the explanation for the comparatively recent establishment of so many houses all over the land engaged in the preparation of medicines in palatable forms.

Another possible tendency of recent origin is seen in the employment of triturates. By the minute subdivision and separation of the particles of a medicinal substance, through the agency of an admixture, it is claimed—and perhaps on a rational basis—that the power and effect of the agent are thereby not only increased but a new action is developed. The time-honored "Dovers powder" is a good example of a triturate. That the trituration gives the combination additional therapeutic effect over the different elements of the mixture is beyond doubt.

The superior action of this form of medication is supposed to be due to the more prompt and thorough subjection of the remedy to the action of the digestive juices.

It is with misgiving that I record in this connection another tendency of the times in regard to medication. I refer to the disposition to be satisfied with impure and otherwise inferior drugs. The extreme desirability of absolutely pure medicine up to the pharmaceutical requirements in potency as well as purity, to him who proposes to cure disease by their use, goes without the saying. It is, however, a palpable fact that physicians as a whole are very mild in their suggestions for a purer and more reliable pharmacy. If they were as decided and emphatic in their demands as the importance of the matter requires, the evil of inferior medicines would

rapidly disappear. A craze on pure drugs would be salutary in its results, both in relation to the sick and to the character and efficiency of the profession.

Clearly purity and potency of medicines should be unhappily what it is not, and the doctors are the fault of it, a marked and decided tendency of modern medication.

82 Park Place.

MEMORANDA FOR READY REFERENCE.

BY ENOS T. BLACKWELL, M. D.,

CEDARVILLE N. J.

The beginning of the healing art must have been from the nature of things experimental and empirical. Certain results following the ingestion of certain substances doubtless suggested their use as remedial means. The observations of medical men for many centuries have been devoted to increasing the sum of medical knowledge, and enlarging the list of available remedies.

In these latter days physiology has become a valuable aid in the indication of nature's processes, and the way in which they are affected by various drugs with reference to their therapeutic effects. However the knowledge may be obtained by the original investigator, it can only be available to the practitioner as he may be able to retain the facts in his memory, or to reproduce them by some method of refreshing this faculty. It must be painfully impressed upon every well-read person that the varied facts brought before his mental vision are many of them lost from the imperfection and limitation of this important function. Upon the remembrance of the busy man, who snatches a moment occasionally to learn the recorded thoughts of writers, the impression is often extremely transient; and if he afterward faintly recalls something in reference to it, the place where he read it cannot be recollected, and he fails to retrace the thought of the author, and his observation is to him fruitless. This is true, perhaps, of all persons whose lives are crowded with a multitude of duties of divers kinds; it is especially so to the physician, who, returning to his home at the close of a hard day's service, wishes to acquaint himself with what is going on in his profession elsewhere. The drowsiness incident to passive exercise in the open air renders his mind little alert; and unaided by some record, his reading is mostly without lasting profit. It may be that a case presents itself to him, in which, from the obscurity of the diagnosis or from the rebellious nature of the disease, resort must be had to various remedies in succession before a cure can be effected. The urgency of some patients is such as to oblige the physician to administer in quick succession every remedial measure which his fellow-practitioners have recorded for his benefit. He may be unacquainted with the way in which the drugs affect the morbid condition, and must be content to rest on the authority of the reporter. Since then we must often prescribe empirically, we shall have a much greater supply of material to guide us, if we have been careful to collect for future use everything available encountered in our researches.

If the physican is a writer, as every observing one should be, he finds the record of the opinions and observations of other writers necessary that he may press them to account, either as supplementing his own views, or, for marshalling in array for their demolition.

As a convenient and satisfactory means of recording what he learns by reading or otherwise, the present writer has used for some years the INDEX RERUM of DR. JOHN TODD. The mass of material already secured has been of incalculable benefit to him in some persistent illnesses in which the old-time remedies were ineffectual, and for which no recent book furnished a substitute. In preparing articles for the press, he is enabled, by its use, to quote without loss of time from authors who have stated their views in transient publications. By this means he made available, in a case of Pott's fracture of the leg, the very efficient apparatus of Dr. Packard, of Philadelphia, by which extension and counterextension of the leg is secured through adhesive plasters applied to the upper extremity of the leg and to the foot, and made to draw in opposite directions by passing the tails over a side-splint, and fastening the opposing ends together. This method was obtained from the MEDICAL AND SURGICAL REPORTER, vol. liv, page 387. It is detailed at length in the author's paper on Fractures in *The International Cyclopædia of Surgery*, vol. iv, page 242. Under the same head, "Fa," I have some other valuable memoranda:—Plaster bandage, method of preparing and applying, (Dr. B. Lee), vol. ix, p. 27,

Phil. Med. Times, Fracture of Patella, cure by adhesive straps united by buckle and tongue (Blackwell), *ib.*, xii, 869. Fractures, fixed dressing for, (Levis's solution—Zinci oxid, 8 oz., glue 4 oz., water Oij. MEDICAL AND SURGICAL REPORTER liii, 655. Fractures, intracapsular, diagnosis and treatment (Levis), *ib.*, liii, 720; Fracture of the Clavicle, Agnew's method with adhesive plaster, *ib.*, lx, 393.

These are a few of many cases I might cite, illustrating the advantage of this plan. I have given in some instances the authority for the statements recorded; and sometimes the very words in which the recommendation is couched. The reader will at once recognize the value of this addition, although it was an afterthought with me. Sometimes I record a prescription, when it is short. This avoids the necessity for looking up the original. A duplication of a fact under different heads is useful—the name of the disease under one, the name of the remedy under another. A reference to lumbago may also be indexed under rheumatism; and ptyalism in one place may be salivation in another, etc.

Whoever adopts and uses the Index, in the way indicated, will accumulate a treasury of valuable information ready to be used on a moment's notice. He will be able to summon to his aid the collective wisdom of many teachers, whose opportunities for observing the effects of remedies have been unrivalled. He will have the satisfaction of knowing that he has availed himself of every hint for the treatment of any difficult case, and need not fear criticism, either scientific or only captious, and will be in condition to pronounce sentence in doubtful cases without danger of successful contradiction. Incidentally, his memoranda will show the relative value of various journals consulted, as to their richness and variety of contents.

—COLD WEATHER.—Do not permit microscopical mounts to be reduced to the freezing temperature. Even those preparations in liquids that do not congeal at 32° F. will be injured by sudden or great changes in temperature.

—BENZOL IS NOT BENZIN, and microscopists should remember it, even if some wholesale druggists do endeavor to sell benzin for benzol. I have seen work spoiled and time and patience lost by those who tried to use benzin for benzol.

CHRONIC CATARRHAL RHINITIS.

BY T. W. CORWIN, M. D.,
NEWARK, N. J.

The term "catarrh" or "catarrhal rhinitis" has been applied to so many conditions of this membrane that it has come to be quite indefinite. Prof. Bosworth has been quoted as saying that there is no such disease. He states that the best definition of the term "nasal catarrh" which he could offer was "something the matter with the nose." The term is however correct enough so far as it goes, and it is simply because the inflammatory lesion is so very frequently *secondary* to the efficient cause that this designation has been criticised.

As a clear notion of the anatomy and physiology of the nose is essential to an appreciation of its pathology, I may be pardoned for mentioning a few details which have attained to especial prominence in this department, and which are not dwelt upon in general treatises. The nasal cavities are limited by rigid bony walls which lie closely approximated. As these walls are further covered with a thick mucous coat, the cavities of the nose are practically only extended chinks, and any considerable enlargements or displacements of one wall, cause it to encroach upon its neighbor. The mucous coat varies somewhat in different parts. In the apical portion of the cavities above the middle turbinated bone, it is comparatively thin. In the lower and middle meatuses it is thick and luxuriant, and toward the naso-pharynx is so abundant as to be disposed in folds. These meatuses correspond to the respiratory region of the organ, which is traversed by nearly the whole of the respiratory current. The membrane attains its greatest development upon the inferior turbinated body. Section of this body shows that its bony constituent contributes but 1–20 of the whole mass. The richness of the membrane in the respiratory tract depends chiefly upon the notable abundance of its blood-vessels. These constitute it an erectile tissue. This tissue has been demonstrated by Dr. Bigelow of Boston prominently, and by Continental observers. It is an abundant cavernous structure, susceptible of inflation. Its greatest development is seen at the posterior extremity of the lowest turbinate.

The olfactory nerves are supplied to the membrane of the superior meatus, and do not reach below. The further nerve supply

is obtained from the fifth nerve and from the Vidian branch of the sympathetic, through Meckel's ganglion. Behind the nose is the naso-pharynx which is practically a part of the nose. I will call your attention to the notable *glandular* development of the mucous membrane of this part. So marked is it, that the aggregation of mucous follicles often forms a prominent object upon the posterior pharyngeal wall near its summit. As this structure is identical with that of the tonsils, it is called the pharyngeal tonsil, or "Luschka's tonsil," after its discoverer.

Physiology of the Nose.—Three prominent functions are served by this organ, namely: Olfaction, Phonation and Respiration.

Olfaction.—The sense of smell, so long considered as the chief occasion for having a nose, is found to be of but secondary importance. Indeed its special nerves occupy only the upper and much narrower part of the organ.

Phonation.—The part taken by the nose in modifying the tones of the voice, while important, will now receive reference merely.

Respiration.—The nose is chiefly useful in connection with the function of respiration. In other words, the nose is an important part of the respiratory apparatus. The largest and roomiest two of its passages, the inferior and the middle ones, afford a channel for the breath. As the air enters the body through the nose, it becomes modified by it in three important respects.

I. As to Temperature.—In the first place, it is raised in temperature. Air which has simply passed through the nose to the nasal pharynx in the ordinary course of inspiration, attains to nearly the temperature of the *expired* air. In other words, almost all of the heat which the air acquires in respiration, is gained in the nose! A remarkable fact! These data have been obtained through the experiments of Aschenbach and of Kayser. These observers aspirated air from different parts of the respiratory passages and carefully noted its modification. When the inspired air was cold, as from 24° to 32° F. the expired air was 81.5° F. When that inspired was from 66° to 69° F. that of expiration was from 90° to 92° F. Yet air which had passed through the nose simply without traversing the passages below, was found to be but 9° to 10° F. less warm! We see therefore that the nose supplies heat to the air—also that this supply is regulated according to the necessity for it. For the figures show that much more heat was supplied when the outside air was cold, than when heated, and that at the back of the organ it was nearly uniform, in spite of the variations outside. The source of this heat is undoubtedly the blood current, since there is no other adequate supply. We also find the blood-vessels distributed in a manner calculated to enable them to serve such an office. Further, Kayser has noticed that when the atmosphere is cold, the blood supply of the turbinated bodies is greater. This brings before us another feature of the blood sinuses—viz.: that they vary as to their fulnesses—that therefore the tissues lining the respiratory tract of the nose are a form of *erectile* tissue, and that their distension and consequently their size, varies with the changing condition of the atmosphere. This control is presumably exercised through the Vidian branch of the sympathetic, the great vaso-motor system of the body. In support of this view, the chief distribution of this nerve is found upon the area occupied by the erectile tissues.

II. As to Moisture.—We find that the air is modified by the nose in another important respect—namely, in that it acquires moisture—in that it acquires a *great deal* of moisture. The same observers, Aschenbach and Kayser, determined the changes of the air with regard to its humidity by methods similar to those used in determining temperatures. They found that whatever its condition as to moisture might be before entering the nose, it always became *saturated* with the vapor of water while traversing it. As it is incapable of absorbing a further quantity, it follows that the whole supply of water, which the air derives from the respiratory tract, is obtained in the nose. This amounts on the average to 5,000 grains daily—nearly a pint! As to the exact manner in which so great a quantity of fluid is furnished we are not altogether assured. The mucous membrane of the nasal fossæ is not very notably rich in gland supply, and such as it has, are similar to those which simply supply elsewhere a coating or mucous for lubrication and protection. However, a French anatomist, Chattelier, has described numerous fine canals running from the lymphatic interspaces of the membrane directly to its free surface, and these are believed to furnish the serous fluid which moistens the breath. When this phenomenon is further considered, it is seen that in the vaporization of so much water much heat must of necessity be rendered latent. It is therefore

obvious that the nasal passages are required to supply *this* heat in *addition* to that referred to.

III. As to Filtration.—Further, it has been noted by the same observers previously cited, that the atmosphere is almost entirely freed from suspended materials, as dust, etc., by the nose. Experiments upon animals whose nasal respiratory passages are of considerable length, show that the air is *entirely* freed from dust.

We find then that the great function of the nose is to prepare the air for the lower passages.

Pathological Anatomy.—This can be readily determined during life. In acute catarrh we note simply the changes incident to inflammation of any mucous membrane, with, however, a predominence of swelling. The swelling is due principally to distension of the vascular sinuses. This condition appears to be associated with vaso-motor paresis. In addition, there usually are present the changes incident to chronic catarrh, for the acute affection is so frequently an exacerbation of the chronic disorder, as to be fairly symtomatic of it.

In chronic catarrh, inspection anteriorly shows usually a deep red, spongy, thick and boggy hypertrophical condition of the membrane over the turbinated bones and the septum. This is apt to be irregularly developed so that sometimes polypoid masses are seen. The surface presents accumulation of inspissated mucus, often firmly attached.

In advanced cases on the other hand, an atrophic condition presents—owing to contraction of the over-grown connective tissue. Atrophy also occurs primarily in some cases where the interstitial exudation chokes off from the membrane its nutritive supplies. The mucous crusts are seen again, but are apt to be more dry and thin and firmly attached.

Inspection posteriorly shows the same conditions except that the color of the membrane is usually pale. The hypertrophy is often found greatest in the spongy tissues at the posterior end of the inferior turbinated bone. Here a globular tumor is often seen which may project into the upper pharynx. The glands of the upper pharynx are frequently hypertrophied so as to form small or large masses of adenoid growth of various forms which may block up this compartment very seriously. There are further found the various other lesions to which the catarrh is secondary, as, quite prominently, deflections of the septum, irregular development of the cavities, polypi, specific ulcerations, fibroids, etc., as well as diseases of the accessory sinuses. The lower pharynx and larynx and sometimes the bronchi also usually present catarrhal conditions.

Symptoms.—The symptoms are locally: Difficulty of nasal respiration; retention of the secretions and efforts at removal; catarrhal conditions of parts below; occasional pain and hemorrhage; impairment of mental activity; reflex nervous phenomena; loss of olfaction and phonation. Constitutionally: anemia.

Difficulty of nasal breathing leads frequently to mouth breathing, by which the air is but imperfectly prepared for the lower air passages. The contact of this air excites pharyngitis and laryngitis, which subsides when nasal respiration is restored. The contact of vitiated secretions with those parts has further influence. (We pass over other characters of the discharge.)

As to local pain and reflex neuroses: these are most likely to occur when the hypertrophied tissues come to impinge upon one another and especially upon the septum. This impaction is often constant, but more commonly it is found during periods of especial congestion, as after exposure or in the course of a "cold." The reflexes are numerous and important. They are such as irritable cough, spasmodic contraction of the throat muscles or the larynx, asthmatic seizures, hay fever, various distributions of anæstherias, of perverted sensation, of neuralgic pain, of nutritive lesions, as acne and pruritus, herpes and urticaria, affections of the eye, the ear and other organs, vertigo, epilepsy, chorea and the like. Congestive headaches often depend on engorgement of the nasal plexuses, and are relieved by local depletion. It is a notable fact that these flexuses are normally distended during menstruation. Mental dulness is frequently attendant upon this affection. Patients complain of inability to concentrate their attention, etc. This symptom has received the name, "aprosexia." It is thought to depend on imperfect drainage of the lymph from the brain by reason of the blockade in the lymphatic system of the nose. Anæmia with its legion of disorders is at times referable to nasal catarrh.

Diagnosis.—The diagnosis can with our present resources be readily made. I refer now not to the diagnosis of the catarrh

which is usually advanced by the sufferer and is sufficiently obvious, but to the more remote *occasions* of this process. The obstruction is determined by observing the freedom of the air current through each nostril separately. The statements of patients as to this matter, and as to their resort to mouth breathing are often altogether untrustworthy, but the history will usually sufficiently distinguish many characters of the discharge.

Our main reliance is upon *inspection*, and this cannot be practically carried out without the assistance of the following agencies:

1st. Suitable specula for expanding the vestibule of the nose.

2nd. A strong light whose rays are about parallel with the line of vision, conditions supplied by an ordinary argand burner with a condensing lens and a head mirror.

3rd. A small mirror for the upper pharynx.

4th. A fairly strong solution of cocaine, as 8 per cent., 10 per cent., or 12 per cent. The use of cocaine has almost revolutionized the practice in rhinology. It acts principally in two ways, both important; 1st, by abolishing sensibility, thus allowing of the necessary manipulation; 2nd, by its wonderful power of firmly contracting the erectile structures, but most important, it may be applied so as to remove the normal turgescence of the membrane at the anterior part of the nose and thus bring into view the condition of parts more remote.

Pathology.—The essential characters of the inflammatory process, whether acute or chronic, are the same here as elsewhere, but their secondary features are modified by the special conditions of the nasal cavities. Of the cardinal symptoms of inflammation the swelling is in this case, perhaps, of the greatest importance. It obtains to a greater degree than in affections of other parts. This pre-eminence is due to the extensive vascular development. The lumen of the vessels becomes enormously increased. The swelling is further dependent to some extent upon exudation; but to a minor degree only. As a result of the acute process the vessel walls lose tone and the swelling becomes chronic, with tissue growth due to the increased nutrition, and after a long time atrophy. The immediate consequence of this tumefaction is obstruction to the passage of air through the nose, for the walls of this cavity being bony, no extension outward is possible.

We have then nasal stenosis developed. This condition is a prominent factor in the further progress of the case. As the air is drawn into the body by aspiration, there is normally some diminution of the ordinary pressure (which the air seeks to re-establish). When the nasal passage is contracted, the air has less ready access and aspiration causes a more decided vacuum to form. The blood presence therefore distends the vessels of the membrane situated behind the stenosed portion and they become enormously dilated. Their tone is destroyed and the condition then persists indefinitely. The relaxed condition also renders the membrane more susceptible to the influences which induce acute catarrh. Thus a vicious circle is established and we have a chronic catarrhal inflammation with acute exacerbations.

The prominent factor in the maintenance of chronic catarrh is therefore, *stenosis* of the nasal passages. The exudation in this affection is a prominent feature, since its disposal involves much difficulty. Owing to this difficulty, and the increased attention therefore given to this symptom, it was for a long time thought to be in excess of the amount of fluid furnished by this membrane in the normal condition. This idea has, however, been shown to be erroneous. The secretion is actually diminished. That which is furnished is also apt to be faulty—to have an undue consistence. It therefore does not flow backward freely as should occur, and requires considerable effort for its removal. When the hypertrophy leads to contact between opposing surfaces, the membrane is irritated and frequently eroded; pain and tenderness are excited; the secretion is further altered and its flow hindered and reflex symptoms are very liable to occur. The pressure between the surfaces varies somewhat according to the congestion present. In consequence of these conditions, there is retention of the discharge, of its more solid portions especially. The fluid part runs off or is dissipated by evaporation. The retained mucus decomposes and becomes very offensive, as well as tenacious and difficult of removal. The disorder frequently extends along the canals communicating with the nose. The eye and ear often suffer by this means.

Treatment.—The key to successful treatment of this affection lies in a just appreciation of its causation. This cause, as has been stated, is in the great majority of cases comprehended under the term "nasal steno-

sis." The removal of obstructions to free respiration in the nose is the great principle of radical treatment, as conducted to-day. This idea does not conflict with the reference of the affection to meteorological conditions which doubtless exercise the greatest influence primarily, but as a result of these influences, nasal stenosis is usually established and becomes the proximate cause of the affection.

Stenosis is the result also of other influences. Thus, deformity of the forward portion of the septum nasi is a very frequent one, and this lesion is frequently traumatic in origin. The formation of polypi or other tumors, the enlargement of the pharyngeal glands, often consequent upon the ravages of the eruptive diseases in the throat—the lodgment of foreign bodies, etc., all act in the same direction. Conditions of the general health exercise a potent influence in predisposing to and in maintaining disease here as elsewhere.

The removal of stenosis demands various kinds of procedure. When of little standing and dependent upon acute catarrh, it will yield to simple means directed to the cleansing of the surfaces, and perhaps including the use of astringents. The general nutrition needs attention as well. But astringents are not regarded so highly as formerly and such medication as has been resorted to with this object are considered to render service rather by reason of their stimulating quality.

Another indication frequently exists and is quite urgent. It is the necessity of relieving *contact* between opposing surfaces. Such contact gives rise to much of the reflex and local suffering attending the disorder. It may not be constant, but occur only during turgescence of the membrane, which, however, is a most frequent condition. It demands the same measures of treatment. When the stenosis is of longer standing, more active measures are used. Medicinal agencies are inadequate and removal of the excess of tissue is resorted to.

For hypertrophies of the mucous membrane and its sinuses, some form of cautery is usually employed. This is effected by application of chromic or of nitric or of glacial acetic acid, and rarely of nitrate of silver. Besides these the galvano-cautery is most depended upon. They are considered to act partly by direct removal of tissue which sloughs away and partly by causing absorption of that in its proximity. The applications are therefore to be limited and should not extend completely over the area to be removed. In some cases the relaxation of the membrane is such that it can be gathered up in a fold; in such cases it is often practicable to remove it by means of the wire snare. This condition is most frequently met at the hinder end of the inferior turbinated body. In adenoid vegetation about the naso-pharynx, removal is accomplished by the snare, by the galvanic cautery, and often by their combination in the galvano-cautery snare. Curettes are however often of service and sometimes forceps are used. Of the means of reducing bony obstructions, I need say little here. The latter are frequently encountered. Various devices are used, as saws, shears, snares, forceps, etc. Prominent among these is the electric trephine. Cases of atrophy of the nasal membrane and erectile tissue are usually a late stage of trouble, and are very troublesome. They call for stimulating measures. Another great principle of treatment here is the maintenance of cleanliness. It is a characteristic of chronicity in inflammations of mucous membranes that their secretions tend to adhere closely, and the progress of a case toward recovery of the membrane is indicated by their becoming fluid and easy of removal. These mucous accumulations injure the membrane greatly, often erode it and are very liable to become offensive by decomposition. It is a cardinal principle to remove them thoroughly before attempting any more radical measures. It is quite the fashion also to combine antisepsis with this effort. Solutions are most used, but oily preparations often act well, while in some cases the offending substances must be directly seized and detached.

Many other indications are presented in individual cases and notably such as demand sedative measures, but as they are not peculiar to nasal affections, they demand no reference. There are a few remedies which appear to act specifically upon the nose and throat after absorption into the blood. These are, most prominently, muriate of ammonia and cubebs.

Prognosis.—All cases are susceptible of relief, and usually of very great relief. The majority of cases are considered curable, but only after considerable time, when the changes are very marked. Cases distinguished by atrophy are most intractable, and often admit of palliative treatment alone.

Society Reports.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Stated Meeting September 11, 1889.

The President, Dr. W. W. Keen, in the Chair.

Dr. Ferdinand H. Gross read a paper on

Hematometra.

(See page 454.)

In the discussion Dr. John C. Da Costa said: I would ask Dr. Gross where he punctured the uterus in the second case? Did he attempt to follow the cervical canal, or did he put the trochar directly into the mass? I congratulate both patients on having fallen into the hands of Dr. Gross, and out of the hands of their previous advisers. Hematometra is not of common occurrence, and when we have it, it is usually due to closure of the entrance; or atresia, so called. The first case described, I think would be found described in the books rather under the head of atresia of the vagina rather than of hematometra. I do not understand how those who had previously examined and treated the case could have overlooked the nature of the difficulty. They would not have done so if they had heard the late Professor Wallace lecture on atresia vagina as he used to describe it, with "the bulging membrane looking like a child's head coming out." If they could not have made a vaginal examination, an examination by the rectum would have shown the uterus above and the soft fluctuating mass below, and made the diagnosis for them.

The second case seemed to be due to closure of the cervical canal. This is more common after the application of solid nitrate of silver than people generally are aware of. There is apparently something particularly vicious about the application of solid nitrate of silver to the cervical canal. Stronger agents may often be used without producing the trouble it does. I do not see how in this case a practitioner could mistake the nature of the trouble. The gravity of such cases often arises from imperfect examination of the parts, and, therefore, knowledge of the condition, and as a result of this—want of timely treatment.

Dr. Lawrence Wolff said: I had the pleasure of examining the second case with Dr. Gross. I assisted him in emptying the uterus, and my curiosity being aroused as to the nature of the chemical changes that had taken place, I secured some of the contents for examination. The microscope showed that there were no corpuscles present. I made the blood test, and secured Teichmann's hematin hydrochloride crystals. While there was undoubtedly blood, there was no hemoglobin but hematin. I think the question is not altogether solved as to what becomes of the serum-albumin in such conditions. The uterus is not prone to take up serum-albumin, but here it had evidently been absorbed, and nothing but globulin and hematin remained, as we found to be the case when the mass was mixed with water, which rendered it turbid, the globulins being insoluble in water. The fact that globulin is not taken up is not generally known. We know that the corpuscles, as a result of pressure, poisons, and other conditions, will break down, and that hemoglobin will be changed to hematin, but it is not generally understood that in hematometra serum-albumin, which is diffusible, is reabsorbed and globulin retained. These facts have a bearing upon various pathological conditions, especially some forms of nephritis, and that is one reason why I have brought up these points in regard to the condition of the blood in these cases.

Dr. J. Price said: These congenital forms of atresia are quite common. In the last few years a great many operations have been done for infantile forms of the female generative organs, and in many of these cases we find atresia. In the last year I have done two sections for regular menstrual molimen without blood. They had suffered from the age of thirteen or fifteen years to thirty-five, without any menstrual flow. In these cases I found atresia with infantile uteri. The appendages were rudimentary. There was no accumulation. In these two cases the results have been quite happy.

A few years ago, a lady asked me to attend her in her confinement. Conception had immediately followed an operation upon the cervix done by an estimable operator. She had been sterile for five years before the operation. Previous to this she had borne three children. She sent for me after she had been in labor for some time. There had, however, been no show. On examination I found a supra-vaginal diaphragm, without the semblance of os or cervix. I made a careful speculum examination, and

sent for a friend, a man of good judgment and experience. The head was engaging, but no os could be found. We made a crucial incision in this diaphragm, and she was delivered of a healthy child without trouble. She made a good recovery, and has since borne children. In this case, although a canal had been left, there were probably some granulations which subsequently closed the canal.

Ten days ago, I operated upon a cicatricial case. The woman had borne four healthy children, but had not menstruated for some years. I found but little accumulation. There had been extensive sloughing, and I had to make a vagina throughout. A portion of the blood had apparently been absorbed. The material found in these cases is usually of a hard character, similar to that found in hemato-salpinx. It will make a black mark, and can be used as a crayon.

The discharges from the tubes of which Dr. Gross speaks, I am satisfied lasted only a short time. The irritation is sufficient to provoke occlusion of the tube, and we have the clubbed condition of the tubes seen in accumulation of fluid in the tubes. The tubes look like the end of an amputated finger. I have here two specimens illustrating this point. The woman from whom this was removed never conceived, there is a semblance of a pavilion. There has been salpingitis and local peritonitis, causing closure of the pavilion. Here you have a broad ligament cyst, an occluded tube, and a typical hydrosalpinx. Schœder gives an interesting discussion of this entire subject, and cautions care in the examination that leakage or rupture may not occur. It is evident from his remarks that this accident had occurred in his hands.

Dr. Gross: In reply to the question of the first gentleman, I would state that there was only a point indicating where the os might have been. I followed this in the direction one would suppose that the canal would take. It was some distance before the trochar reached the cavity.

In regard to the first case, an examination per rectum might have revealed a small uterus if the fluid had been contained only in the vagina. This case was, however, of six or seven months' standing, and the secretions, after filling the vagina, had also dilated the cervix and uterus. Here the term hematometra is also used. When the vagina only is filled, it is an hematocolpos. To be more exact, unless you object to long names, the term hematometrocolpos would express the condition when both vagina and uterus are involved.

I am obliged to Dr. Wolff for his interesting remarks in regard to the character of the fluid. His remarks make the report of the case more complete.

Periscope.

Bacteriology of Drinking-Water.

In the N. Y. *Medical Record,* Oct. 5, 1889, there is an admirable paper on the bacteriological tests of drinking-water by Dr. Edward K. Dunham, of New York, the whole of which is eminently worthy of careful perusal, and the concluding portion of which we lay before our readers.

If we trace the history of a given sample of water, says Dr. Dunham, we shall arrive at a point in that history when the water must have fallen as rain. Since water, when it evaporates, leaves behind it all suspended matter, it follows that any bacteria found in rain-water must have been washed from the air, or from the surfaces with which the rain came in contact. They were either in the atmospheric dust, made up of fine dry particles wafted into the air by currents, or they were upon the water-shed. It so happens that bacteria are not all equally capable of preserving their vitality when subjected to the desiccation which must precede their presence in floating dust, and it follows therefrom that rain-water, except under extraordinary circumstances, will contain only species included in a group provisionally designated as "air bacteria," without implying that they are found only in the air. And, conversely, if all the bacteria in a sample of water are of a species included in this group, the deduction that it has been exposed to none but aërial contamination appears reasonable, no matter how numerous the individual bacteria may be.

If we next imagine that the rain-water has fallen upon the ground and thence is washed into streams, ponds, or open wells, it is evident that it will carry with it those bacteria which can readily be detached from the vegetation or the soil over which it has passed. In brook or pond-water we may, therefore, look for not only air bacteria, but bacteria belonging to a second group of species representative of surface drainage.

While a portion of the rain-water runs

from the surface, another portion sinks into the ground and eventually becomes blended with what is called the "ground-water." During its passage through the soil, most, and probably in many cases all, of the bacteria contained in it are caught in the interstices of the ground, or are subjected to unfavorable conditions and die. Observation has shown that ground-water is usually free from bacteria, or contains them in but small numbers; but when the soil is very pervious the ground-water may yield bacteriological results approximating those indicative of surface drainage.

The ground-water underlies a layer of soil rich in bacteria, and is exposed to many chances of receiving them on its passage toward the surface, where alone it can be of domestic use. And it is during this passage to the surface that it is exposed to the greatest risks of contamination with sewage or excrementitious matter, which are especially liable to contain noxious bacteria. In such a water the bacteriological test is capable of detecting the contamination and of determining its nature with considerable precision.

From a bacteriological point of view, admixture of sewage with a water can be injurious only when that sewage contains noxious bacteria. If, through any process, the sewage be freed from such bacteria, it will be deprived of all bacteric infectious qualities. The most common natural process by which sewage is freed of bacteria is filtration through the soil. If all the bacteria are removed the sewage can contain no pathogenetic species, but if they are not all removed and the sewage passes into a water-supply, the latter will be in danger of infectious contamination so soon as the sewage contains pathogenetic bacteria. The detection of the contamination of a water-supply with sewage is of particular interest because of its relations to the possibility of infection with typhoid fever following the drinking of such a contaminated water.

We know of no general natural habitat of the typhoid bacillus. It may be that, in the future, some natural home or mode of development of that bacterium will be discovered. When that knowledge has been acquired the bacteriological test of water can be applied so as to make practical use of it, but for the present we must consider the discharges from individuals suffering from typhoid fever as the source from which typhoid bacilli might gain access to drinking-water.

If the water were free from bacteria before the entrance of the typhoid bacilli, and the latter were not mixed with other species of bacteria, their detection would be simple and certain, and with the finding of them a bacteriological examination of the water would come to an immediate conclusion. But in actual cases the typhoid bacilli are associated with large numbers of the fecal bacteria, and this mixture is disseminated through a large bulk of sewage; the chances of identifying the typhoid bacillus are inestimably diminished by these circumstances, and we are, therefore, constrained to condemn water containing fecal bacteria, or those forms of putrefactive bacteria which are frequently found in sewage, even though they themselves may have no pathogenetic qualities, and even though the source of the water was apparently pure.

Simple and clear as are the principles underlying the bacteriological test of water, it does not seem superfluous to consider a few typical illustrations of their application to cases met with in actual practice.

I. A sample of water was found to contain an average of 496 bacteria in one cubic centimetre, a very large majority of which belong to a single species—micrococcus caudicans—a very common air bacterium. There were but few other species present, most of which were recognized as common air species.[1] The inference from such a result is direct: The water, a pure water, had been exposed to the air and then remained subject to conditions favorable for the development of the bacteria which had fallen into it until they had increased to the number found. This conclusion was confirmed by the fact that the sample, as was afterward learned, had come from a tank which was filled with water previously subjected to a very intelligent process of filtration. Some of this same water, after being bottled for a short time, contained 3,970 bacteria per cubic centimetre, among which five species were recognized, the majority of the individuals belonging to the single species caudicans. No reasonable sanitary objection could be raised against this water, either before or after it had been bottled, although the number of bacteria found in both samples exceeded the usually accepted limit for good water.

Many of the air bacteria seem, after a

[1] Bacillus luteus, yellow sarcina, micrococcus cereus flavus, and some not named.

time, to die out when introduced into water, as is exemplified by a sample of rain-water, which immediately after collection, during a gusty thunder-storm, contained 5,940 bacteria; while, after standing protected from dust for a few weeks, the number had fallen to two. On the first examination there was a large number of species present; on the second examination only a single species, common in both air and water.

II. Water from a sylvan brook, swollen after a heavy rainfall, contained over two thousand bacteria to the cubic centimetre, a large number of which proved to be bacillus subtilis, a species abundantly found on vegetation and in earth. There was also present a species frequently found in soil. No other species other than air species were found, and it was, therefore, concluded that the large number of bacteria was due to surface drainage innocent of injurious qualities.

III. A brook was examined at its source, where the water ran from a loosely covered cleft between two rocks; again about half a mile from its source, after it had wound through a grove and open fields; and again at a third point, about three-quarters of a mile beyond the second place of collection, and several hundred feet below a point where it received the drainage from some half-dozen dwellings. At its source it contained 250 bacteria, among which there were several air species, a few of the more common water bacteria, also occasionally met with in the air, and a few earth species. Samples from the second point of collection contained 532 bacteria, similar in character to those at the source, but the water and soil species were relatively more abundant. At the third point of collection the number of bacteria had risen to 4,773, and, besides the species found above, there were both fecal and putrefactive species present.

The correspondence between the results of the bacteriological examination of this brook and the history of the water is so close that, if we knew only those results and the order in which the samples came, we should be obliged to construct a history of the water essentially identical with that of this brook.

IV. The water-supply of a certain town is drawn from a series of driven wells, which are, with the single exception of one used for making observations on the level of the ground-water, connected in such a way that the water is pumped from them all collectively. A sample of water taken from the main at the pumping-station contained two bacteria per cubic centimetre, while a sample taken from the observation-well contained five thousand. But the bacteria in the latter sample were all of one species—namely, the same species which has already been mentioned as persisting in a long-preserved sample of rain-water. According to our principles of interpretation, these samples must be regarded as equally free from suspicious contamination. The five thousand bacteria were due to an adventitious inoculation of the test-well with a harmless species capable of thriving under the conditions there prevailing. After stating that the bacteria present were of a single species, it is superfluous to add that the well was kept covered.

V. A deep artesian well, situated in the immediate neighborhood of a field irrigated with the sewage from a large public institution, was used as the water-supply for the inmates. The water had been repeatedly declared unsafe because of the high yield in total solids, chlorine, and ammonias obtained on chemical analysis. It was examined bacteriologically and found to contain very few bacteria, none of which represented species indicative of sewage contamination. There was no clinical indications that the water was unwholesome. In this case it appears that the natural filtration of the water through the soil sufficed to free it from bacteria.

VI. A stream which was drawn upon to furnish water to a town, was suspected of being contaminated with sewage because of an outbreak of typhoid fever in that town. Chemical analysis failed to furnish evidence of any such contamination, but the water was found to contain large numbers or bacteria belonging to a putrefactive species common in sewage. This result, while not demonstrating the presence of typhoid germs in the water, arouses a strong suspicion of a sewage contamination, which alone would be sufficient to declare the water untrustworthy.

In conclusion, it is evident that the bacteriological examination of a water cannot, save under exceptional circumstances, pronounce a direct verdict as to the sanitary value of that water. Its legitimate province is the discovery of the relations existing between the water and the natural or fortuitous distribution of the various species of bacteria. The significance of those relations must be

determined by our knowledge of the causation of disease.

Nurses' Training School in Camden, N. J.

A school for nurses has been established in the Cooper Hospital, Camden. This is the first school of the kind organized in Southern New Jersey. The first session of the school commenced October 4.

About twenty candidates, mostly women personally known to and vouched for by members of the hospital medical staff, are enrolled as pupils. The school year will be divided into fall and spring sessions, the first embracing the months of October, November, and December, and latter March, April, and May. Lectures will be given by the members of the medical and surgical staffs of the hospital on Tuesdays and Fridays of each week between 4 and 5 o'clock. The lecturers will include the most prominent physicians, surgeons, and specialists of Camden, and eminent visiting members of the profession. Skeletons, charts, and manikins have been prepared to illustrate these lectures, and as the scholars advance in their lessons they will be given practical experience in the wards of the hospital, and in the pharmacy, and chemical and dissecting rooms. The school is under the personal direction of Dr. D. Strock.

Upon the completion of the course of studies, if the student can pass a satisfactory examination, a certificate of fitness to perform all the duties of a trained nurse will be given. A list of graduates and their addresses will be kept, and applicants for a skilled nurse will be directed to the graduates who are known to be available at the time the application is made.

Improvement in Inguinal Colotomy.

Dr. Charles B. Kelsey, of New York, says, in the *Medical Record*, Oct. 12, 1889: In the last few inguinal operations I have performed, I have adopted the following plan: The incision is that of Cripps—across a line from the anterior-superior spinous process to the umbilicus. After getting the sigmoid flexure outside the body, a hair-lip pin is passed under it in the following manner: It is entered through the skin on the side of the wound toward the median line, and at the junction of the lower with the middle third of the incision. It perforates first the skin, next the parietel peritoneum, next the mesentery of the gut close to the bowel, and at the junction of the lower and middle thirds of the exposed loop, next the parietal peritoneum on the other side of the incision, and finally, the skin. By this means the gut is so firmly held in position that it cannot be dislodged by any vomiting, and a perfectly satisfactory spur is formed, which will prevent any passing of fecal matter beyond the opening. After this procedure I have never been troubled either by prolapsus of the mucous membrane, or the passage of feces from the colon into the rectum. With this modification I now adopt a running suture instead of about fourteen interrupted ones, to join the parietal peritoneum to the visceral layer, and to the skin. A rapid operator can easily, in this manner, complete the entire technique of inguinal colotomy in ten minutes, and to this extent reduce the necessary shock.

Disarticulation of the Humerus with Resection of the Articular Eminences.

Dr. Raoul discusses this subject in a Paris thesis. The disarticulation of the forearm, he says, is always preferable to amputation of the arm at its lower third. 1. It is less often followed by death. 2. Leaving the arm longer it gives greater leverage. 3. It preserves the lateral eminences and so assures the fixity of an artificial limb. It should be performed whenever the soft parts are long enough. If this is impossible, the arm should be disarticulated at the elbow, if the skin is still sufficiently long, and the articular eminences resected. This operation offers the advantages of a disarticulation, but requires a centimeter of integument less. To perform the operation, a circular incision is made, as in ordinary disarticulation, but from one to one centimeter and a half higher; the trochlea and the condyle are sawed off at the level of the tuberosities of the humerus. Then the prominent cartilage is resected with pliers all around the surface of the bony section, and the parts united with catgut sutures—first the muscles, then the skin, in such a manner that the cicatrix will not be transverse but antero-posterior.—*Gazette Médicale de Paris*, August 17, 1889.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

CONSANGUINEOUS MARRIAGES.

There is a widespread belief that the marriage of persons nearly related by blood is likely to result in offspring of imperfect physical or mental development. This, most medical men know to be true—not for the reason to which the result is usually attributed by the laity, but because consanguineous marriages concentrate in the offspring the physical or mental defects or weakness of the parents, as both parents are likely to have the same sort of defects or weakness, while in other marriages the risk of a coincidence of the kind is comparatively slight. But, real as is the danger in consanguineous marriages, the mere fact of consanguinity is not in itself a danger to the offspring. There are many proofs of this in history, while an interesting addition to them may be found in a recently published book by His Majesty Kalakaua, king of the Sandwich Islands. This book is entitled *The Legends and Myths of Hawaii*, and it is edited by Hon. R. M. Daggett, late United States Minister to the Hawaiian Islands. In it the statement is made that "In the royal families, to subserve purposes of State, father and daughter, brother and sister, uncle and niece frequently united as man and wife. The children of such unions were esteemed of the highest rank, and, strange to say, no mental or physical deterioration seemed to result from these incestuous relations." In commenting on this statement a reviewer in the *Nation*, Sept. 26, 1889, says: "There seems to be no doubt of the accuracy of the facts here stated. The magnificent physical development, the clear and active minds, and the noble manners of the higher chiefs are matters well within the memory of the present writer and of other former residents of the group."

This contribution to our knowledge of the subject of consanguineous marriages is especially interesting as coming from a country where admixture with a foreign population, and the abandonment of their ancient social customs, has been followed by a deterioration of the native race which is as pitiable as it is unmistakable.

COMPETENCY OF MEDICAL WITNESSES.

The Supreme Court of Wisconsin has recently rendered an opinion which is of interest to medical men. The substance of this opinion is that the testimony of a medical witness who has had no practical experience in the treatment of cases of poisoning, and who testifies only from memory and his knowledge of what medical works and medical instructors teach on this subject, "is, at best, hearsay, and inadmissible in a criminal trial for murder by poisoning." The opinion narrates the main points of a case of this kind in which the plaintiff in error—that is the defendant at the first

trial—had been charged with murdering his wife by poisoning, and had been convicted. The principal medical witness described the symptoms of the patient and testified to the symptoms of arsenical poisoning. His testimony was objected to by the defence, on the ground that he was not an expert. The Court sustained the objection until the witness could be further examined as to his qualifications to testify. It was in evidence that he was not a graduate of any medical college, but had been practicing for twenty-five or thirty years. He could recall no case in which he had treated arsenical poisoning before. The Court admitted his testimony, and largely upon the strength of it, and that of another medical man who was equally inexperienced in arsenical poisoning but who also claimed to be able to describe its symptoms, the defendant was convicted.

The Supreme Court in passing upon this case ordered a new trial, on the ground that the Court below committed a serious error in admitting the testimony of the medical man who was in attendance on the case, in view of the fact that he said that he had never personally seen a case of arsenical poisoning before.

A very careful review of this judgment is contained in the *American Law Register*, for August, 1889, prepared by Richard G. Morrison, Esq., of Minneapolis, Minn. In this, after a very careful comparison of a large number of cases more or less similar in character, the opinion is expressed that actual experience should not be held to be absolutely necessary to render a physician competent as an expert on a particular question, though the lack of it should be considered by the jury, in connection with his other qualifications, in determining the weight to be given to his testimony.

In this opinion we entirely concur. It seems to us preposterous that a medical man whose experience had covered a number of years in medical practice, and who was able to describe the symptoms of arsenical poisoning—or any other—should not be a competent witness simply because he had never before in actual practice seen a case of such poisoning. We can understand that there may have been some prejudice in the present case against the physician who was the chief medical witness because he was not a graduate of any medical school, but this does not seem to have been the consideration which led the Supreme Court of Wisconsin to its decision. It certainly is not mentioned, and the presumption would be in favor of any medical man who had been practicing for a long time in any one particular place.

It is not always easy for medical men to follow the affirmation of the Courts in regard to matters of medico-legal interest, and sometimes the deliverances of Courts of last resort impress them as bearing the mark of human fallibility. But this is not an experience of medical men alone; other men have at times cause to dissent when even a Supreme Court lays down the law. In any case, however, this is the law, and law-abiding citizens may well know and submit to it.

RETURN OF THE HOMŒOPATH.

The *New York Medical Times*, a journal whose circulation is almost exclusively among homœopathic practitioners and which until recently at least, was avowedly homœopathic, has contained in the numbers for September and October, 1889, articles and editorials discussing the possibility of union of homœopathic with regular practitioners of medicine. The writer of the articles, a Southern physician, claims that there never will be at any future time a possibility of perfect unison between the two "schools," as he terms them; and he suggests the establishment of "mutual respect and co-operation when the good or satisfaction of patient or physicians may require," to be further cemented by the formation of a "Union Medical Association" to include all classes of physicians. On the other hand, the Editor of the "Times" holds to the belief

that the word "homœopath" is in itself the one obstacle in the way to a future alliance, and, acknowledging its lack of significance, proposes to homœopaths that they abandon this designation. Then, it says, the bonds of professional union can be extended over the present apparently unbridgable chasm.

In this, our contemporary is entirely right. The attitude of the regular school of medicine toward the sects is charitable but it cannot be weak. One step is indispensable to any form of union with them and that is for them to abandon their sectarian names. In the case of most so-called homœopaths, as we have steadily urged in the REPORTER, the title is either a mere misnomer or a fraud; and in either case it must be abandoned.

This subject has recently been quite fully discussed by the Philadelphia County Medical Society, and the sentiment was unmistakable that the regular school can have nothing to do with the sects so long as they insist upon a special designation. It is surprising that men of excellent judgment in general can for a moment entertain the idea of any harmonizing of the regular profession with irregulars—who will not themselves come in if they believe their exclusive dogmas, and who ought never to be admitted if they do not. In the first case the conscience of the irregular debars him, and in the second the conscience of the regular ought to perform this duty for him.

The more this subject is considered, the clearer it becomes that it is now about time for the Old School to let the homœopaths work over it awhile by themselves. The case is plain to any one who has a logical head. The Old School stands on a broad scientific basis; the sects insist on something else. It makes no difference what that something else is—it cannot be scientific, and it must be abandoned. There are indications now that intelligence and conscientiousness are beginning to work in the ranks of so-called homœopaths; and there is reason to believe that before long the best among them will summon courage to take the inevitable step, and sever themselves from those the shame of whose ignorance or want of conscience they must share so long as they keep them company. This we say—as we have said it before—with no unkind feeling toward those whom we regard as entangled in error, and mainly to counteract the possible influence of a recent plea for "union" and "harmony" which might mislead the sectarian as to the real attitude of the mass of physicians toward them. Here and there a man may miss the real issue; but the mass of the Old School understand it perfectly well, and will not be blinded to it by any specious argument.

BOOK REVIEWS.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the REPORTER.]

RECHERCHES CLINIQUES ET THERAPEUTIQUES SUR L'ÉPILEPSIE, L'HYSTÉRIE ET L'IDIOTIE. Compte rendu du Service des Enfants Idiots, épileptiques et arriérés de Bicêtre pendant l'année 1888. (CLINICAL AND THERAPEUTICAL INVESTIGATIONS ON EPILEPSY, HYSTERIA AND IDIOCY. Report of the Service for idiotic, epileptic and Backward children of the Bicêtre Hospital for the year 1888.) BY BOURNEVILLE, Physician to the Bicêtre, and COURBARIEN, RAOULT and SOLLIER, Internes. Volume IX, 8vo, pp. lix, 92, with twenty-five illustrations. Paris: *Progrès Médical*, 1889. Price, three francs, fifty centimes.

The first part of this report is taken up with an account of the service during the year 1888, and gives an interesting but brief outline of the methods of instruction pursued with the children. Pichery's system of gymnastics, which is largely used, is described and illustrated by a number of cuts. The authors think that the study of words should be begun with the consonants, not with the vowels; that the syllables composed of one consonant and one vowel should be articulated first, and that labials should precede all others; and they add that isolated syllables are less easy of articulation than repeated syllables. The opportunities for studying the classes of disease mentioned may be inferred from the fact that, on December 31, 1888, there were three hundred and seventy-eight children in the service.

The second part of the book is devoted to the clinical aspect of the cases. Dr. Bourneville first discusses "New cases of Idiocy with Pachydermatous Cachexia." These are cases of cretinoid or myxœdematous idiocy, which the author thinks are much more common than one would suppose from the small number of patients of this kind admitted to asylums. Several cases of the kind are described, and two reproductions from photographs of cases are given. In none of the living cases, the author says, has it been

possible to *feel* the thyroid gland, and in three autopsies its absence was demonstrated.

Bourneville and Courbarien declare that consanguineous marriages are productive of epileptic, hysterical, idiotic and imbecile children, only when the parents are unhealthy: healthy parents, as a rule, can procreate only healthy children. The third chapter is on "Epilepsy and Fronto-facial Asymmetry." Bourneville has tried bromide of nickel in eighteen cases of epilepsy: in one case there was progressive diminution of the number of attacks, until they disappeared completely and remained absent for three years; in one case there was improvement, which is still marked under the influence of purgatives and douches; and in one case the number of attacks remained the same. In all the rest (fifteen cases), the remedy aggravated the disease. The results obtained, therefore, have been very different from those of Da Costa. The book concludes with a chapter on perversion of instincts, and with an appendix.

The book will be read with great interest by those who have charge of the same classes of patients, and it should stimulate them to make better use of the material than has been the custom hitherto, at least in this country.

PHOTOGRAPHIC ILLUSTRATIONS OF SKIN DISEASES. An Atlas and Text-Book combined. By George Henry Fox, A. M., M. D., Clinical Professor of Diseases of the Skin, College of Physicians and Surgeons, New York, etc. Second series. Complete in twelve parts. Parts 1–10; each 10x11½ inches, containing sixteen pages of text and four colored photographic plates. New York: E. B. Treat. Price, $2.00 per part.

This is a second issue of the plates and text on skin diseases first issued by Dr. Fox five years ago. It has the merits of the original issue, with the added advantage of some remodelling and enlargement. It is a very handsome piece of bookmaking, and the text and plates are full of interest and instructiveness.

The plates are reproductions of photographs taken from patients, and they are colored so as to make the resemblance to the actual conditions more clear and more striking. In all of them, the conditions are very faithfully portrayed, and in some the representations are remarkably vivid. The text is well fitted to the pictures, and the whole book makes an impression like that of a good series of clinical lectures. We can heartily recommend this work to the attention of our readers, feeling sure that it is calculated to be helpful in the diagnosis and treatment of cases of a sort which are very troublesome to most practitioners.

CORRESPONDENCE.

Antiseptics and Country Obstetrics.

To the Editor.

Sir: I have been reading the interesting articles of Drs. Mitchell and Kemper upon the subject of "Antiseptics in Normal Labor." Not being much of a writer, but a weekly reader of the Reporter, a deep thinker and a constant worker as a country practitioner, I must say I heartily coincide in their idea of non-asepsis as regards sublimate solution, etc., in cleansing the parturient canal after delivery. For my part, I will say: I have clean hands; I make as few examinations as possible, and ten times out of ten the mother and child will get along all right, even cheer the father's heart the next day, and the old man will say: "Doctor, I will pay you when I dig my potatoes this fall."

My experience in country practice in the way of obstetrics in the past eleven years has amounted to the number of 1,008 births, and I have not lost a mother in confinement or childbed fever. Of course, I have had the usual amount of still births from premature or lingering labor, but these would not amount to twenty-five. I have had, I think, every presentation, and have used podalic versions several times, without injury to mother or child. I keep two pair of forceps, and must say I have never had the pleasure or misfortune—whichever you may call it—to give them an introduction in their calling. However, I don't know how soon I may have to use them, as I consider them invaluable in time of need.

As Dr. Mitchell says, a country doctor is called one hour in the home of poverty, the next where all is surrounded with the luxuries of wealth. Of course, this makes the doctor a creature of circumstance. To illustrate: I was called to see a poor family in the country, living in a cabin 8 x 10. The mother was in confinement with the sixth child. After staying four hours, delivery came about all right. Nothing would do now but that I should take breakfast, as it was about daylight. I seated myself at the table by the side of the bed and cleverly commenced eating, when I heard a cluck, cluck, and turning my head I discovered a big dog devouring the placenta under the foot of the bed. Suffice it to say, my appetite failed at once, and I put off my meal until I arrived at home. To conclude, I will say: Keep your hands clean, be attentive, and avoid too much interference.

Yours truly,

John T. Mason, M. D.

Milledgeville, Ohio.

Oct. 14, 1889.

The Celebrated Painting of Rembrandt, called the "Anatomical Lesson," has been bought, it is said, by Mr. Ellesworth for the Institute of Art, of Chicago. It formerly belonged to the Princess de Sagan.

Notes and Comments.

Pilocarpine in Traumatic Tetanus.

Dr. L. Casati, of Forli, has reported three cases of traumatic tetanus which were cured by hypodermic injections of hydrochlorate of pilocarpine. In the first, large doses of chloral hydrate and bromide of potassium were given internally, and chloral was injected into the veins; the symptoms, however, became worse. Then belladonna ointment was rubbed into the skin over the affected muscles, one-half of a grain of watery extract of opium was exhibited every two hours, and one-sixth of a grain of hydrochlorate of pilocarpine was injected every two hours, night and day. In six days the tetanic contractions had ceased, but violent delirium came on, probably as the result of the belladonna frictions. This was checked by paraldehyde, and complete recovery took place. In the next case, treatment was limited to the pilocarpine injections, and the symptoms gradually disappeared. In the third case, which was one of great severity, eleven and one-third grains were injected in fifteen days, with complete success.—*British Medical Journal*, June 15, 1889.

Spontaneous Rupture of the Heart.

At a recent meeting of the Anatomical Society of Paris, M. Mallet reported a case of spontaneous rupture of the heart. The patient was a man, 79 years old, who came under the care of M. Letulle for symptoms of oppression, cough, and arterio-sclerosis. On the sixth day he was seen to become suddenly pale, oppressed, and to move his arms in an epileptiform manner. The whole attack lasted three or four minutes. As he had slight albuminuria the attack was thought to be uræmic. Fifty-three hours afterward this patient suddenly died, and at the autopsy was found a rupture of the heart with an effusion into the pericardium of thirteen ounces of blood.

The facts noted in this case of rupture accord nearly with the conclusions reached by Odriozola and stated in his recent thesis. As regards the etiology, it is interesting to note that the aorta in this case was atheromatous and the left coronary artery almost completely obliterated near its origin. The seat of the rupture was on the anterior face of the left ventricle; the opening was vertical and zigzag in shape, but of unusual length—fifty-five millimeters. The longest opening in a case cited by Odriozola was five centimeters. As to the symptoms, it must be admitted that the first crisis marked the beginning of the lesion, and that then followed it a phase of calm—a phase which has been insisted upon by Albert Robin.—*Bulletin Médical*, June 26, 1889.

The Pulse During the Puerperium.

As a rule, the pulse begins to slow down immediately after labor, and slows steadily for the first eight days of the puerperium. It is most rapid at the beginning of the first puerperal week, least rapid at its end. This slowing is equally marked in primiparæ and multiparæ, and amounts in the week to nine or ten beats per minute. Beginning at 61, it falls to 50–51. There is a diurnal variation in the pulse-curve as in the temperature-curve. The pulse is slowest at midnight and quickest at 8 A. M.; it rises most from 6 A. M. to 8 A. M. and from 12 to 2 P. M. The difference between the maximum and minimum rate any one day is on the average seventeen beats (60–77). The pulse rises after meals. The slowest pulse taken during these observations was 36, which was found on two occasions in nursing multiparæ on the seventh day. Blot and Depaul have observed a pulse of 35 in the puerperium, Olshausen and Quinquaud 34, while McClintock has reported a pulse of 30 after the birth of triplets. This is the slowest puerperal pulse yet recorded. The main cause of pulse-slowing in the first puerperal week is probably the altered condition of the blood, while physical and mental repose is probably a subsidiary factor. Has the pulse-rate any prognostic value? As long as the pulse remains slow the puerperal patient is not suffering from any serious febrile disturbance, but as soon as febrile symptoms appear the pulse rises. If there is elevation of temperature without correspondiug rise of pulse, the febrile disturbance is probably only ephemeral. Of course a diagnosis or prognosis cannot be safely based upon the consideration of a single symptom; the pulse-rate must be considered along with the temperature-curve, and the other symptoms subjective and objective.

After *regular* labors the temperature rises continuously and reaches its maximum in

six to seven hours, then it falls steadily for ten to twelve hours, and reaches its minimum sixteen to nineteen hours after delivery. The remission is greater than the rise, because at the conclusion of labor the temperature is above the normal. In primiparæ the temperature two to three hours after delivery is almost half a degree higher than in multiparæ, but in eighteen to nineteen hours the effects of the more severe labor have passed off and there is no longer any marked difference between them. After *irregular* labors the temperature is ½° to 1° higher than after regular labors, and it takes a proportionately longer time to fall to the normal. A normal temperature-curve for the first twenty-four hours is a favorable prognostic as far as it goes, but of course is no guarantee of a subsequently favorable puerperium. — *Montreal Medical Journal*, June, 1889.

Extirpation of the Parotid Gland: Recovery.

Dr. Polaillon, who has done many delicate operations in the neck, reported to the Academy of Medicine of Paris, August 20, 1889, a case of complete extirpation of the parotid gland, and presented the patient upon whom the operation had been performed. The boy had been sent to him four years ago by Dr. Descroizilles. He was then five and a half years old, and had a cystic tumor, as large as an orange, in the right parotid region. The tumor was recognized as an adenoma of the parotid, with multiple cysts, and probably, also, with some nodules of enchondroma. The tumor projected externally, lifting the lobule of the ear, but it did not compress the facial nerve.

On August 18, 1885, Dr. Polaillon exposed the tumor by a **T**-shaped incision, and then dissected it with the thermocautery and bistoury down to the internal carotid, which could be seen beating in the depth of the wound. A small portion of the parotid, which appeared healthy, was allowed to remain. Cicatrization resulted by first intention. The cheek and the lips on the right side were incompletely paralyzed. About one year afterward there formed, under the cicatrix, some small cysts which lifted the skin and made it thinner and thinner. The skin having broken, some vegetations of malignant appearance developed at the seat of rupture; at the same time the subjacent tissues became indurated slowly. Without waiting for this relapse to develop to a dangerous degree, Polaillon performed a second operation on December 15, 1886. He removed all the hardened tissues, and then, with the sharp curette, he cleared the whole parotid bed, protecting the carotid with a small elevator. The remaining fibres of the facial nerve were destroyed, and facial hemiplegia was complete after this second operation. The child has been well for nearly three years. The facial hemiplegia has not at all improved. Nevertheless the orbicularis palpebrarum has regained sufficient contractile power to close the lids nearly completely. The duct of Steno is atrophied, and it is impossible to discover its buccal orifice. The patient does not complain, and has never complained, of having a drier mouth than before the operations. The other salivary glands supplement the absent parotid. The sensitiveness of the cheek is unaltered. The nutrition of the tissues does not appear to have suffered. The upper right incisor, however, has not yet erupted, although the child is now nine and a half years old. The upper canines on each side are wanting. Finally, under the skin of the right cheek veins are perceived, which do not exist on the opposite side; and on the internal surface of this cheek, are seen varicose veins. These peculiarities are explained by the development of veins destined to supply the circulation in the right facial vein and in the parotid veins, which were destroyed by the operation.—*Bulletin de l' Académie de Médecine*, No. 33, 1889.

The Bactericide Action of Serum.

Buchner (*Münchener med. Wochenschrift*, No. 24, 1889) was able to establish, first of all, that bactericide properties reside in animal blood in a defribinated condition. He thus comes to results similar to those of Nuttall. The blood of rabbits and dogs showed this action in about the same degree. The power of resistance of the separate kinds of bacteria was, however, very different. It was least in the typhoid bacillus, the cholera bacillus, the bacterium coli commune, and the bacillus fœtidus; but the bacillus pyocyaneus and a bacillus resembling that of typhoid fever and dwelling in the intestines, were more difficult to destroy. Splenic fever and swine erysipelas

(*Schweinerothlauf*) occupy a middle position. The bactericide power of the blood is preserved for a long time by cooling the blood, but is destroyed by heating it to 131° F.

The author has also tested the constituents, particularly of the cell-free blood-serum, for supposed bactericide properties. It was shown that in such experiments an antagonism occurs between the nutritive and killing properties of the medium. Thus, in the cell-free serum of rabbit's and dog's blood, the bactericide action, which otherwise was continually demonstrable, was made to disappear completely, in favor of the nutritive action, by the addition of peptone.

Considering the fact that blood frozen and again thawed loses its bactericide action, the better nourishing properties restored through the destruction of the red blood corpuscles might have been brought into play. Cell-free serum, on the contrary, does not lose its action through freezing, but does lose it by being heated for half-hour to 131° F. To what constituent of the serum the bactericide properties must be attended, is still not clear. They are not destroyed by neutralizing the serum up to the point when it gives a faint acid reaction, nor by dilution with four times its volume of water. If, after repeated freezing and subsequent thawing, a layer of serum occurs, then the action seems to be preferably confined to the lowermost layers, perhaps as a property of the albumin of the serum which lies there. At all events, the bactericide action is to be regarded as a function of the *living* blood-serum.

Buchner was unable to demonstrate similar properties in the serum of oxen and of horses.—*Centralblatt für die med. Wissenschaften*, August 10, 1889.

Movement of Eyelids after Decapitation.

It is reported from Negaunee, Mich., under date of September 30, that a man fell between two freight cars on a moving train and his body was frightfully mangled, while his head was completely severed from the trunk, and lay several feet from the track.

A train hand picked up the head and was horror stricken to see the eyelids close and again open and partly close again. This was seen also by the engineer and the brakeman. All three were badly frightened. This sign of consciousness was given several minutes after the head was severed from the body. The three witnesses are said to be reliable men, and it would be interesting to know the exact facts of the case and the explanation of what seems impossible from a physiological standpoint. It is certainly contrary to the observations of Dr. Loye on death by decapitation, as explained in his book reviewed in the REPORTER, June 1, 1889.

Music as a Medicine.

In an able article on music in *Science*, Oct. 11, 1889, Major J. W. Powell, says:

Disease and wounds and pain and death were the heritage of the early man. Whence these evils came he knew not; why they came he could not tell. How they were to be driven away was the enigma of all savage thought. Through an illogical philosophy, the origin of which is a long and strange story, he came to believe that diseases were living beings; that toothache is the pain wrought by the gnawing mythic worms; that the cough is caused by mythic insects; that headache is caused by invisible mythic ants; and that all diseases and all pains are produced by these mythic agencies. And he tried to drive them away by shrill shrieks, by mad howling, and by horrid imprecation. Then he sought to gain the aid of the friendly spirits of the world,—the good mythic beings. To him the rhythm of the dance and the chant was the language of joy. So he sought to woo these friendly spirits by using this language of joy; and, when wearied with his own efforts at driving away the maleficent spirits, he turned to the dance and the chant, and with them called for the beneficent spirits. In this manner the sylvan man came gradually to believe in the direct efficacy of dance and music as a medicinal agency. Dance and music are the quinine and calomel of the savage,—the "water-cure," the "faith-cure," the "blue-glass cure," the "mind-cure," the "Christian-science cure" the "youth-restoring elixir," the panacea for all human ills. When the poor diseased people recovered, the joy of recovery became associated with music. The welcome to health and companionship which the poor invalid received was given in dance and music.

NEWS.

—Dr. J. Madison Taylor has removed to 1504 Pine St., Philadelphia.

—Dr. Hirst has removed to 248 South Seventeenth St., Philadelphia.

—The Dominion Department of Agriculture has been advised of the arrival at Deptford, England, from New York, of another cargo of animals infected with pleuro-pneumonia.

—Dr. Carl Koller, who has achieved such world-wide renown in the discovery of the application of Cocaine as a local anæsthetic has been appointed Instructor in Ophthalmology at the New York Polyclinic.

—Professor Virchow telegraphs from Berlin that the Organizing Committee of the Tenth International Medical Congress has been constituted by the election of himself President, and Dr. Lasar Secretary General.

—On October 14, Dr. W. E. Hughes and Dr. J. M. Anders were elected to fill the vacancies in the staff of the Philadelphia Hospital (Blockley) caused by the death of Dr. E. T. Bruen and the resignation of Dr. Wm. Osler.

—A company is putting down a shaft into Grand Avenue Cave, four miles from Mammoth Cave, for the purpose of bringing up the air and putting it into the rooms of a large hotel which they propose to build, both as a pleasure-resort and sanitarium.

—Diphtheria in malignant form is prevalent in Gallitzin, Pa. During the last three weeks the deaths have averaged three or four daily, and at least fifty cases are reported in the town. Four families, with six or seven little ones each one month ago, were said, October 15, to be childless.

—As Dr. Hosmer A. Johnson was making out a deposit ticket in the First National Bank, in Chicago, October 14, a thief grabbed his money and ran. The thief was caught, and refused to give his name. He said he took the money because he had a wife and child starving to death.

—A prominent member of an Indian tribe who claimed to be a doctor was killed lately. Things had not been going well with the Indians for some time, and the doctor was regarded as culpable for it, and at a meeting of the tribe four men were appointed to execute him; which they duly did.

—Dr. D. W. Harrington, 55 years of age, died in Lockport, New York, Oct. 11, from an overdose of morphine. Dr. Harrington was graduated at the Medical Department of the University of Buffalo, in 1871. He leaves a wife and son, Rev. Frank P. Harrington, Chaplain of Deveaux College, at Suspension Bridge.

—The suit of Dr. Frost, of Baltimore, against Dr. John L. Seitz, of Harrisburg, mentioned in the REPORTER, October 19, ended October 15, as it was shown that Dr. Seitz merely acted as a promotor for Dr. Frost by agreeing to introduce him to one hundred Harrisburg families. This was substantiated by affidavit, and the court dissolved the injunction.

—In Philadelphia a committee of residents of Germantown advocated, before City Councils' Water Committee, October 15, a better supply of water, both in quality and quantity, for that district. The Germantown citizens asked for the adoption of a plan that contemplates the erection of a new reservoir at Shawmont, at a cost of $500,000, and the introduction of filters to purify the water.

—The seventh annual meeting of the Ohio State Sanitary Association will be held in Dayton, Ohio, November 21 and 22, 1889. The President is D. H. Beckwith, M. D., of Cleveland, and the Secretary R. Harvey Reed, M. D., of Mansfield, Ohio; their headquarters will be at the Beckel House. All persons interested in having and maintaining good health are invited to attend the sessions of the Association.

—Among recent appointments of Johns Hopkins men are B. Meade Bolton (assistant, 1887–88), director of the Department of Bacteriology in the Hoagland Laboratory, Brooklyn, N. Y.; William H. Howell (Ph. D., 1884, and associate professor), lecturer on physiology in the University of Michigan; Henry Sewall (Ph. D., 1879, and recently professor in the University of Michigan), professor of physiology in the College of Physicians and Surgeons, Baltimore.

—Dr. Charles L. Weed, a well-known oculist of Philadelphia, died October 15, 1889, at the age of 32 years, of heart disease, after an illness of three months. He was graduated from Jefferson Medical College in 1883, since which time he has been prominently identified with specialists on the eye and ear. Dr. Weed was, until his death, chief of the eye department of the German Hospital, and had charge of a similar department of the John B. Stetson Dispensary. In his profession he was the associate of Dr. Charles S. Turnbull.

NEW AND RELIABLE RECIPES FOR PHYSICIANS PRESCRIBING.

In order to get the full therapeutic effects, physicians will please specify (WARNER & CO.) when ordering or prescribing.

☞The coating of the following pill will dissolve in 4½ minutes.☜

PIL: CHALYBEATE COMP.

(WARNER & CO.)

Nux Vomica is added as an ingredient to Pill Chalybeate to increase the tonic effect when desired.
Composition of each Pill.—℞ (Chalybeate Mass.), Carb. Protoxide of Iron, gr. 2½., Ext. Nuc. Vom. gr. 1-6.

DOSE—1 to 3 Pills.

Most advantageously employed in the treatment of Anæmia, Chlorosis, Phthisis, Scrofula, Loss of Appetite, etc.

PIL: ANTISEPTIC.

Each Pill contains: Sulphite Soda, 1 gr. Salicylic Acid, 1 gr. Ext. Nuc. Vomica, ¼ gr.

DOSE—1 to 3 Pills.

Pil. Antiseptic is prescribed with great advantage in cases of Dyspepsia attended with acid stomach and enfeebled digestion following excessive indulgence in eating or drinking. It is used with advantage in Rheumatism.

Prepared by WM. R. WARNER & CO.

PIL: ANTISEPTIC COMP.

(WARNER & CO.)

Each Pill contains: Sulphite Soda, 1 gr. Salicylic Acid. 1 gr. Ext. Nuc. Vomica, ⅛ gr. Powd. Capsicum, 1-10 gr. Conc'd Pepsin, 1 gr.

DOSE—1 to 3 Pills.

Pil. Antiseptic Comp. are prescribed with great advantage in cases of Dyspepsia, Indigestion, and Malassimilation of Food.

Supplied upon physician's prescription by all leading druggists.

1228 MARKET ST., Phila. 18 LIBERTY ST., New York.

EVERY PHYSICIAN

prescribing Cod Liver Oil (and who does not?) wants to know that his patients get the best that can be obtained. This is effectually secured by specifying **" BAKER'S "** whose firm (established in 1830) have given the greatest attention to the improvement and perfection of this all important remedy. In the various conditions in which Oleum Morrhuæ is indicated the Practitioner must decide the best form of administration. To meet such conditions we offer:

BAKER'S COD LIVER OIL.

BAKER'S EMULSION WITH HYPOPHOSPHITES OF LIME AND SODA.

Baker's C. L. Oil with Ext. of Malt.

Baker's C. L. Oil, Lime and Wild Cherry.

Above goods are accessible through the wholesale trade to all Retailers, and may be prescribed with the utmost confidence as to Purity and Excellence.

JOHN C. BAKER & CO., PHILADELPHIA, PA.

Physicians and Students of Medicine

are invited to attend the meeting of the

THERAPEUTICAL SECTION

OF THE

POLYCLINIC MEDICAL SOCIETY

AND THE

Lectures on Practical Subjects

by members of the Faculty, delivered under the auspices of the Society,

——On Tuesday Evenings——

throughout the Winter Course, at the College Building,

N. W. Cor. Broad and Lombard Sts.

For announcement of full course of instruction, for physicians only, apply to

L. W. STEINBACH, Secretary.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders**, is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds**, handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe, and healthful Home.

CHOREA.—PARALYSIS OF ANTERIOR TIBIAL NERVE.

BY HENRY M. LYMAN, M. D.,
CHICAGO.

PROFESSOR OF PHYSIOLOGY AND DISEASES OF THE NERVOUS SYSTEM, RUSH MEDICAL COLLEGE, CHICAGO, ILL.

Chorea.

Gentlemen: The first patient I present to you this afternoon is 19 years of age, and from the mother we gather the following: His father is living, but has been suffering from rheumatism for fifteen years, being first attacked when 35 years of age. His state of health before that was good. This young man was attacked with rheumatism in the joints two years ago, and was compelled to stay in bed for three months. He then got up, went to work and worked four months, when the disease returned. The second attack was so severe that it was hard work for him to get about, being able to walk a little, but not much. It took him more than three months to get over the second attack, and he has not been well since that time. Now, this boy is the son of a father who has been suffering with rheumatism more or less for the last fifteen years. Two years ago he was attacked with rheumatism in the joints, which was followed by swelling of the joints, tenderness, and more or less debility, lasting for a number of months. He seems to have recovered from the first attack and was about for a time, when a second attack occurred from which we are told he only partially recovered at the end of three months. Ever since the patient has been in a debilitated condition, with incapacity for locomotion and active exertion. About four months ago he manifested a new series of symptoms. He began to move and turn the fingers little by little, and this gradually increased. About this time he had a fuss with his companions, after which he grew

nervous, the agitation of the fingers growing worse. The mental excitement consequent upon a little unpleasantness with some of his companions developed these nervous, jerky movements which you see. Four months ago he could not walk very well; he felt dizzy, and in some instances would fall. You notice the involuuntary jerk in his leg, arm or foot, from time to time, showing a disturbance of the nervo-muscular apparatus. His mother thinks he is growing worse. She tells us that things drop out of his hands, and that the right hand is worse than the left. We will ask him to hold a glass of water with the right hand. You notice the awkwardness with which he holds it. As he changes the glass from the right to the left hand you observe there is a jerk of the head and neck; he seems to move the whole body. We also learn that there is some difficulty in his speech; that he cannot speak as clearly and distinctly as he used to, and it is gradually growing worse. He sleeps fairly well, but towards morning wakes up, throws himself around in bed, and is more restless than he should be. In the mornings he is cross; nothing satisfies him. After the first hour he feels better. Observe also the expression of his countenance—that is worth fixing in your minds.

Can any of you from this history give me a diagnosis of this case? What shall we call this disorder? I am not surprised that you hesitate; the visible phenomena are not as distinct in this as in many cases of the disease. It is a case of *chorea*, and a very interesting one it is in many points of view. It is not interesting as a specimen of the peculiar movements of chorea,—that is true. It is a very easy thing to make a diagnosis where you have a typical case of choreic movement, but there are cases of chorea in which the movements are not so conspicuous, but in which other phenomena are more prominent, and this is one of them. In the first place, the connection between the disease and rheumatism is marked. I told you that he has been suffering with rheumatism for two years, after which symptoms of chorea manifested themselves. This shows very distinctly the relationship which we so frequently discover between chorea and ordinary rheumatism; so much so that chorea is by many writers ranked as a sequela of rheumatism. Another point is the fact that one side of the body suffers more than the other; and in this case it is the right side. He handles any article that you give to him better with the left than with the right hand. That illustrates the tendency of the disease to be one-sided. The disorder is sometimes met with affecting one side only of the body—a hand or arm will be in a state of movement and incapacitated for use, while the corresponding member is in good condition: a hemichorea. Then, again, you notice that the jerk is one of the evidences of a tendency to irregular movement in this case. Another fact worthy of your notice is the debility and incapacity for use of the limbs on one side more than on the other, which exists here in a marked degree. This is true of certain cases of chorea; the paretic condition of the muscles is a marked feature of the disorder; so much so in young children that when you find what is called partial paralysis involving one or more of the limbs of the patient without any apparent reason for it, you should suspect the existence of chorea; what is sometimes spoken of as the paralytic form of the disease in contradistinction to the jactitatory form of the disorder where the ordinary movements are so conspicuous as to enable us to make a diagnosis at once. This resembles in that respect those cases of paralytic chorea.

I desire to call your attention to another feature of the case,—the effect that is sometimes experienced by the brain. Chorea is a disorder which manifests itself conspicuously in the muscles of locomotion and of movement. It is the fact in the majority of instances, however, that it is not the spinal cord and the muscles connected with the spinal centers alone that suffer, but the muscles of expression are affected; those muscles that are connected with the brain through the facial nerve are involved to a very great extent in many of the cases, and as a consequence of the enfeeblement of the facial nerve and of the muscles connected with it, there is a loss of the natural expression of countenance. The patient seems dejected, debilitated, or apathetic, or has even a silly expression of countenance, and if you converse with him you not infrequently discover a corresponding debility in the mental processes. He no longer exhibits that mental vigor which is characteristic of health, and sometimes there is such a grave departure from the normal standard that he is almost insane for the time being, under the influence of the cerebral weakness which comes as a part of the disease.

Now, these tendencies are strikingly illustrated in the case before you. The expression of the patient, the history the mother gives of mental disturbance occurring during the morning hours rather than at other times of the day, are proof of this. In the morning when the patient awakens, somewhat debilitated, a number of hours having passed without anything to eat, where there is defective digestion and nutrition, you will find him complaining bitterly of bad feelings, uneasiness, peculiar sensations; he is fretful and cross. This fretfulness and wearisomeness and the general bad feeling continue until the child has had something to eat and has digested his food sufficiently to be renewing the stream of nutrition that is required for the sustentation of the brain.

With regard now to the treatment of such a case as this. The treatment should be two-fold. It should be directed towards the symptoms of the disease itself, and also towards the predisposition which exists and is dependent upon defective nutrition, especially with reference to the rheumatic diathesis. As far as the treatment of the jactitation is concerned, very little is necessary, as there is not much of it. The thing that is most important here is to build up the patient, increase the integrity and functional capacity of his brain and spinal cord generally. That can best be accomplished by the administration of arsenic and tonics, cod-liver oil, a nutritious diet, milk, cream, and butter in abundance. All these things must be administered for a long period of time. Where the patient fails to respond in three months to that course of treatment, or does not improve, it is well to add strychnia to the treatment. Chronic cases after having been treated in the manner indicated will begin to improve much more rapidly if you add small doses of strychnia to the medicine. In a case like this it would be well to commence with the fortieth of a grain of strychnia, three times a day, and increase it to the twentieth of a grain if necessary. You do this for its tonic effect. Instead of increasing the jactitation in the chronic cases, it gives more steadiness to the muscles. Chorea is a disease of debility, and anything that increases the vigor will steady the nerves of the patient, and this is what you do when you administer a drug like strychnia. It increases the vigor of the spinal cord and brain. In addition, the patient should be given quinine, iron, etc. He should go out in the open air a good deal, and should be warmly clad. Generally in those cases, where there is a tendency to the establishment of chronic rheumatism, or relapse, the treatment I have indicated is the treatment that may possibly prevent these relapses.

You will find in the treatment of chronic rheumatism that cod-liver oil is one of the most useful remedies that can be given to obviate the tendency to recurrence of the rheumatic paroxysms.

The question arises in this case, whether the heart is diseased. I find after examination no evidence of disease of the heart; though it is a common thing in chorea to meet with valvular disease of the heart. Little varicose nodules form upon the margins of the valves of the heart, these are sometimes detached, and emboli are washed by the current of blood into the smaller arteries of the brain and serve to produce thrombosis there. The interruptions of the circulation in the brain sometimes occur to such an extent that some writers have thought this to be the cause of chorea. But there are many cases in which the cerebral disturbance is not so marked as in this case, and in which there is no disease of the heart. The heart here is not affected, consequently there can be no plugging of vessels in the brain from embolic fragments derived from the valves of the heart. The disease is part of a disease of the general system and is consequent upon the direct effect of the poisonous blood upon the brain and of the nerve centers generally.

Acute Chorea.

The second patient I show you presents the features of a case of acute chorea. It is impossible for the patient to keep his hands still. His shoulders shrug, his fingers twitch, and his mouth is more or less distorted from time to time, showing plainly the involuntary movements of the muscles. The patient, a boy 10 years of age, has been troubled this way for about three weeks. Children between the ages of seven and twelve are the children most frequently brought to our clinic with this disorder. He was attacked about the time that the public schools commenced, and had had no sickness previous to that. We have no history of lameness, stiffness, or of rheumatism. There are no evidences of cardiac disease beyond a rapid, violent beat of the heart.

As a general thing acute chorea lasts for two months or more. The general average

of a large number of cases collected by different observers is something over sixty days. Between sixty and seventy days is the usual duration for cases of chorea. Some of them recover in much less time than that; while other cases of the disease continue for a longer period of time, and occasionally we meet with cases that remain permanent. But the vast majority get well after such a uniform period that we feel disposed oftentimes to look upon the disease as self-limited.

So varied are the modes of treatment in vogue—with about the same result—that we are tempted to believe sometimes that treatment has but little effect upon the duration of the disease. I do not know but that this is a fact. Nevertheless you should not on that account neglect treatment; for it is very necessary, and the reason lies in the predisposition of the patient. In the other patient there was a predisposition to rheumatism. In a very large proportion of cases there is some hereditary defect; the children are members of families in which consumption, rheumatism, or some of the evidences of constitutional weakness or predisposition to the disease are met with. Now and then this condition of the bodily tissues and organs demands your careful attention as physicians. You should therefore pay particular attention to the building up of the system by giving tonics and restoratives that will make the child permanently stronger; in that way you will do the patient a great deal of good.

I should advise that the child before us be given Fowler's solution in full doses, and along with it iron and quinine, and a good diet. The child seems to be tolerably well nourished; so it will not be necessary to resort to oils, but certainly the mineral and vegetable tonics should be given.

With regard to the dose that may be given: large doses are the rule. Four drops of Fowler's solution are an ordinary dose of the drug. You may begin with four drops of the drug with a child of this age. They tolerate the remedy very well indeed; then you may increase it to 15, 20, 25, or even 30 drops. You should examine the patient every day or two in order to ascertain whether any symptoms of poisoning are apparent. If you see redness or puffiness of the lids and other symptoms of irritation manifesting themselves, you should cease to advance with the drug. But it is remarkable how tolerant these patients are of this medicine. You may give the drug in this way for a number of weeks with advantage. Do not be alarmed at a discoloration of the skin which sometimes takes place in cases of this kind. I hope we shall have an opportunity of showing you the effect of that during the winter—a peculiar discoloration of the skin that follows the use of Fowler's solution. It is transitory, and it does no harm, and the benefit to the nutrition of the patient is so correspondingly marked as to justify such large doses.

Paralysis of the Anterior Tibial Nerve.

This patient, two weeks before the development of the disorder which we find, had rheumatism involving some territory in the right side of his body, but not apparently implicating the head or thighs as near as we can learn. It then shifted itself so that he could not place one leg up over the other. He could not extend the foot, and that paretic condition of the muscles of the leg has remained ever since. Standing in front of him we notice the muscles of the left leg are not as large as those in the right. There is not much difference in the firmness of the muscles on either side. Extension of the toes is imperfectly performed. The extensor muscles of the toes are partially paralyzed. When he walks, the toes drag, because he cannot extend them in such a way as to catch them up, consequently he has to move the whole thigh in order to get the leg up high enough to prevent the foot from dragging and the toe from catching. It is by no means a paralysis of the whole side, so far as the movement of the hip and knee-joints is concerned; it is that form consequent upon inability to raise the toes sufficient to give freedom to locomotion.

The paralysis is one which involves those muscles upon the anterior aspect of the leg and foot. Now the question is: What has caused that paralysis? It is not a paralysis involving the whole trunk of the nerves. The nerves involved are derived from the sciatic nerve trunk, but the branches of the sciatic nerve that are distributed to the muscles above the knee are all perfect in their function; there is no failure of muscular contraction above the knee, so that it is not a paralysis of the whole trunk that has taken place. It is, therefore, a case of peripheral disease of an inflammatory character, involving the anterior tibial nerve. It is not

the result of injury, or of any local disorder, as we have no history of either. And on feeling the parts we do not discover any evidence of present tenderness in the muscles, or in the sciatic nerve trunk. It is a peripheral disorder of this particular branch.

When you have a peripheral disorder of this kind, that cannot be referred directly to injury, you must look for some constitutional cause. In the majority of cases the constitutional causes that operate to produce such inflammation (when you exclude traumatism) are rheumatism and alcohol. You may have it as a consequence of the action of other poisons in the system. A local inflammation or paralysis may occur as a consequence of diphtheria, measles, typhoid fever, small-pox—all these exanthematous diseases may be followed by peripheral disorders of this kind; but there is no history of the kind here. There is, however, a history of rheumatism. The patient has rheumatic pains in other parts of his body, these pains shift their locality from time to time, and the suddenness of onset also marks the rheumatic substratum of the disorder; so that we must have here a rheumatic inflammation of the branches of the nerves distributed to the muscles that extend the foot. There is one thing to be taken into consideration in connection with this also, namely, that there may be a concurrent effect produced by the habits of the patient. We learn that this man is in the habit of taking a glass of distilled spirits of some kind every day, and has been doing so for a long period. This might create a predisposition to inflammation of the peripheral nerves. Many patients who indulge in this way for a long period of time suffer a great deal of pain, and sometimes paralysis is more or less complete. This used to be spoken of as rheumatism, but we have now learned to identify such symptoms with the consequences of alcoholic indulgence and as one of the features of chronic alcoholism. In short, I am a little suspicious that in this case we have to deal with that, as well as with a rheumatic diathesis.

The treatment should consist in the withdrawal of all alcohol. In the majority of alcoholics the withdrawal of alcohol is followed by recovery in the course of a few months at the furthest. Where there is rheumatic inflammation, it is necessary to resort to the ordinary treatment for rheumatism. We must reform the habits of the patient in the matter of drink, and give him salicylate of sodium. It would be well to give half a drachm of the salicylate of sodium, every three hours, so that he will get two and a half or three drachms in the course of a day, until symptoms of intoxication are produced with the drug; then the frequency of the dose can be diminished, giving it three times a day. As soon as the pain is relieved you can cease the administration of salicylate; but it would be well to give him—for two weeks at least—tonic doses of iodide of potassium and guaiac, to prevent relapse.

For the relief of the paretic condition of the muscles electrical treatment should be employed. The Faradic battery is the one that you should use in such a case as this. Apply a current to the muscles of sufficient strength to produce muscular contraction, and no more. Do not cramp the muscles, but give the electricity in such a manner that you will see the muscles twitch in response to the current. When you reach that point allow the current to pass over (five minutes at a time) the affected muscles. At the end of that time stop the application. If the patient is so situated that you can get at him, you should treat him three times a day, but in ordinary Dispensary practice you cannot do it more than once a day.

533 West Adams St.

CATARRHAL JAUNDICE.—LEAD POISONING.—TYPHOID FEVER.

DELIVERED AT THE PENNSYLVANIA HOSPITAL
BY ARTHUR V. MEIGS, M. D.,
VISITING PHYSICIAN TO THE PENNSYLVANIA HOSPITAL.

Catarrhal Jaundice.

Gentlemen: This patient was admitted two days ago. He is 24 years of age, single, born in Germany and has been three months in America. He is employed in a morocco factory. His family history is good. He does not use tobacco nor whiskey. He had an attack of pneumonia when ten years of age, and another at 18; he had scarlet fever at 12. His present attack began four days before admission with vomiting, diarrhœa, and chilly sensations, but without distinct chill. Two days later, he noticed that he was becoming yellow. He had no cough, but suffered with pain in the abdomen during this time. On admission his tempera-

ture was 97°, his pulse 52, his respiration 24. His tongue was pale and clean. I show you here his urine, which is rather high colored, but otherwise not unnatural in appearance. I will test it, to see if it gives the reaction for bile. I place some urine on this plate, and add a little nitric acid. I allow the acid and urine to gradually mingle, and you can now see a slight prismatic play of colors. We do not see this in normal urine.

To-day his tongue is moist and not tremulous. His conjunctivæ are quite deeply tinged with yellow. There is also some slight yellowish tinge under the tongue. His skin over the whole body shows the same greenish or deep-yellow color. Proceeding now to make a physical examination, I notice two things in connection with his heart. In the first place its action is very slow. Yesterday while resting quietly in bed his pulse was 44, and to-day it is the same; there is besides at the apex a faint, flowing systolic murmur, but as the heart sounds are clear and their rhythm natural, I judge that this is merely a so-called "anemic murmur," heard frequently in those whose blood is poor in quality. Anteriorly the percussion resonance is good and equal on the two sides. The respiratory sounds are also good, with clear vesicular expansion, which is equal on the two sides. Posteriorly, following my usual plan of percussing, I find the resonance normal in the three regions in which I percuss. We do not catch the clear sound heard in front because of the thick muscular tissues covering the back. The liver dulness in the nipple line should commence at the sixth rib and extend to the costal edge, a distance of four inches. Here, however, the dulness begins in the fourth interspace, or slightly at the fourth rib, nearly one inch too high. This cannot be due to a consolidation of the lung, as I have excluded the presence of any lung trouble. The dulness extends one and a half inches below the border of the ribs. I should say, therefore, that the liver is enlarged, though, I cannot feel it on palpation. The splenic dulness is completely marked by tympany. Yesterday, I thought there was some enlargement of the spleen, and it would be likely to be so, as in these cases with depression and slow pulse the spleen is apt to be swollen, for then the internal organs are congested, and the blood is apt to stagnate in them.

Now, what is the matter with this man? I should say that since his admission he has had no diarrhœa; in fact, he has had but one movement of his bowels since then, and his stool was white in color. Ever since his admission, he has had a subnormal temperature. Now, his jaundice might be due to serious disease of the liver, or to some obstruction of the bile-ducts, a catarrhal condition existing there. This latter, I believe it to be, a plugging of the gall ducts by a catarrhal inflammation. The prognosis in such a case is good. In regard to treatment, we have given him the one-sixth of a grain of calomel with five grains of bicarbonate of soda every two hours, to deplete his portal circulation. We will continue this for a few days, and then give him some dilute nitro-muriatic acid to stimulate his liver, ten minims three times a day. In the course of a few days he probably will recover.

Lead Poisoning.

The next patient I shall show you was admitted on the ninth of October. He is 52 years of age, single, born in Ireland, and has been seven years in this country. He has been constantly employed in a paint factory up to six days before his admission, when he was compelled to stop work. His family history is good. He uses whiskey and tobacco habitually. He is complaining of cramp in his belly, constipation and some giddiness. His tongue is pale and tremulous. His temperature on admission was 97⅕°.

Now, what have we here? The history of the case leads us to nothing, except that he is accustomed to the use of whiskey. At present he is constipated and suffering with belly-ache. He says that twice before he had a similar attack. He is rather pale; his pulse is good and natural; his arteries are somewhat atheromatous. He has worked in a paint factory for the past seven years where he was constantly handling lead. We must see if this has had any influence in the production of this trouble. In examining the gums we discover a distinct bluish line just above the teeth. The presence of this line depends largely on the patient's habits. If he is cleanly and uses his brush it is often absent. We must therefore distinguish the true line of chronic lead poisoning from that often found upon the deposits of tartar upon the teeth. This can be done by scraping the surface slightly, when if it is upon the teeth it will be removed. The blue in this case persists after scraping, and is therefore in the gum itself. There is

another point I wish to call your attention to before sending the patient away. The belly in lead poisoning is said to be scaphoid, at times is so much so as to rest upon the spinal column. As a common thing I do not find this to be the case, and you can see that this man's belly is rather full. There is also marked tympany here, which is likewise said to be absent in this condition. If the poisoning has gone far one of the characteristics is a dropping of the wrist due to a partial paralysis of the extension of the hand. Frequently this cannot be seen, but if we test the strength of the muscles we can discover some weakness. This man is considerably stronger in the flexion of his hand than in the extension.

Chronic lead poisoning shows itself usually in one of four different forms. It appears either as lead colic or colica pictonum; as asthralgia or severe pains in the joints; as some form of paralysis, of which the wrist-drop is the most common; or lastly, it may appear as the so-called encephalopathy, where the patient is suddenly seized with convulsions arising from no apparent cause. The lesions here are nil, as in a case of simple epilepsy. These forms are said to be most common in the order I have given them. Tanquerel says that the asthralgic form is the second most common, but I have never seen but one case, while I have seen many of lead colic and paralysis and one of the encephalopathy. I should say, therefore, that this order does not hold true in this country, but that paralysis was the second most common form and asthralgia quite rare.

The symptoms of chronic plumbism are varied. In the first place the patient ordinarily is pale. Then the blue line is present on the gums. The pulse is sometimes said to be slow though this is not a marked feature. There is usually constipation. We must then take into consideration the sources of entrance of the poison into the system. There are some trades more liable than others to produce lead poisoning. Thus it is often found among photographers, and lapidaries, who are accustomed to use a leaden wheel in their work. It is common among painters and workers in white lead factories. Plumbers and gasfitters frequently suffer, and weavers also from the use of a leaden shuttle. Then printers from handling type, and workers in pottery are often victims. One of the worst cases I ever saw in this hospital was in a potter who handled the material used in glazing the vessels. File-makers and paper-hangers frequently suffer, and likewise tailors. I recall a severe case occurring in a tailor admitted to the hospital some time ago. Dr. Penrose, the resident at that time, on inquiry found that the man was in the habit of biting off his thread. On investigating the matter we learned that all of the common forms of black thread are weighted with lead, and this was the avenue through which the poison entered his system. The poisoning not uncommonly arises from the use of cosmetics, and from the drinking water which has been conveyed in leaden pipes. The water of the Schuylkill contains considerable sulphuric acid which produces a deposit of the insoluble sulphate of lead within the pipes thus rendering them innocuous. The purer the water, the greater danger there exists of lead poisoning.

The prognosis in chronic lead poisoning is bad under the conditions in which we usually find it. If we could remove the patients from the sources of poisoning we could cure our cases, but they almost always return to their trades, and in the course of time return suffering with a new attack. The prognosis, therefore, should be guarded.

In regard to the treatment there are three indications to be met. In the first place we must relieve the pain, which at times is exceedingly severe. Then, second, the extreme constipation must be treated, and thirdly we must give something to eliminate the lead from the system. We give opium for the first mentioned purpose, ten drops of laudanum every two hours, or the one-eighth of a grain of morphia two or three times a day or a hypodermic of one-sixth of a grain of morphia. We must avoid overdoing the matter so as not to produce narcosis. For the constipation, Epsom or Rochelle salts are sufficient, one-half ounce in the morning. There need be no haste in treating this condition. To eliminate the lead from the system the best remedy is the iodide of potassium. We have not given this to the man as yet. We shall give him to begin with five grains three times a day and follow later with some tonic, as iron.

Typhoid Fever.

This man is 26 years of age, a Candian, and a student of dentistry. He has been a teacher for the past four years, and has been four weeks in Philadelphia. His family history is good. He uses neither whiskey nor

tobacco. His illness began one week before admission with fever, malaise, and diarrhœa. His tongue is dry, furred, brownish white in the center and red at the tip, and tremulous. There is no urinary disturbance. The heart, lung, and liver examination is negative. The spleen is marked by tympany. His belly, which is full, is covered with rose-colored spots which disappear on pressure. His complexion is fairly good. The diagnosis in this case is very easy. My reason for bringing the man before you was to show to you a typical exhibition of the rose-colored spots of typhoid fever. Murchison says that the number of spots is inversely proportionate to the severity of the case, but our observations are exactly opposite to his. I do not remember to have seen full eruption in a mild case. This man had a temperature of 104⅖° on admission, and it has never fallen below 101⅗°, a quite high fever. He has no bronchitis, and is doing well.

In the case which I next bring before you, and which was admitted on the twenty-ninth of July, the diagnosis was very hard to make. The patient is a mulatto, and has had typhoid fever. In a negro the rose-colored spots are always absent, and his complexion is never the typical one of typhoid fever. I thought for a time he had some form of tuberculosis, especially as his lungs were seriously involved. He is now recovering, however, and is gaining flesh and strength. I bring him before you to show the long duration of his fever. You see the period of subnormal temperature he has passed through, and I would call your attention to the fact that a patient is by no means convalescent until the temperature after being subnormal rises again to the natural point and continues normal for at least several days.

Sense of Taste in Criminals.—Dr. S. Ottolenghi, a pupil of Professor Lombroso, has studied the sense of taste in criminals compared with that of other individuals. He says that in criminals the sense of taste is manifestly weak relatively to that of ordinary individuals; there is, again, a difference less marked between occasional delinquents and those who are habitual or born delinquents. Female criminals have the sense of taste still more obtuse than men of the same category. The author concludes from these remarks that this diminution in the sense of taste in criminals depends on a defect in the cerebral cortex.

Communications.

THERAPEUTICS, AND FALSE THEORIES.

Introductory Lecture at the University of Pennsylvania, October, 1889,

BY H. C. WOOD, M. D.,
PROFESSOR OF THERAPEUTICS.

Reported by J. Howe Adams, M. D.

Gentlemen: As we meet here for the first time I would put to you this question: "Why do you come here?" As intelligent men and students, you reply, "Because we wish to study medicine." But I persist, "Why do you wish to study medicine?" Again you reply, "Because we want to cure disease and relieve suffering." Ah! you have struck the keynote of the profession; without this apology for his existence, the physician has no right to be. Unless he can accomplish this result, he has no mission, no business in the busy world. Without therapeutics the physician is powerless to fulfill this purpose; hence to you as students this branch is all-important; it is imperative that you conquer its intricacies to reach that high position in the profession which you are all determined to hold.

Hence I feel that a little time spent in showing you how to study therapeutics will not be wasted, for it makes all the difference in the world as to the way in which we approach this branch, whether it is a pleasant, instructive task or a drudgery which becomes so irksome as to be almost imperatively shirked.

Firstly, sheer hard work is necessary at the outset; for you must learn many things which are arbitrary, which cannot be reasoned out. Learn first the classes of drugs and the meaning of their titles; then learn the individual drugs by heart. If necessary, write them on your wall and study them as you pace up and down your room. Then do not attempt to master the physiological action by rote; instead, study the symptoms of every remedy, especially when given in poisonous doses. You cannot reason these phenomena out; there is no necessity in our minds why opium in large doses should benumb mind and body; it is simply a fact, and only hard application is going to impress it on your memory. When you are perfectly familiar with the symptoms of a drug, then you must inquire, how does this

remedy act to produce these results; experiments or experience have shown that there are a certain number of ways to effect this; now, which is it? You eliminate those ways which therapeutists have shown require different conditions to act, and by direct and indirect reasoning you reach certain conclusions. These conclusions form the physiological action of the particular drug under consideration.

This was not the way in which the science has always been pursued; it is a development of the century in which we live. How was it when the first man was sick? Undoubtedly he was attended professionally by the first woman and was given more or less relief. How did the old lady, for she was most likely old by this time, reason: Adam was sick, he had certain symptoms, I gave him an herb or root dug from the ground, or possibly some excreta from an animal; he got well, hence when Adam has that disease or those symptoms again, that drug or root or excreta will cure him. And the old lady jotted this fact down in her memory. Seeing the disease, giving the remedy, and getting the relief, was the natural outcome of such experience.

On these principles, therapeutics began to grow and develop into a so-called science. The motto of the therapeutics of that day was, if you will pardon my quoting Latin, "*Post hoc propter hoc.*" This idea is all wrong; it is most uncertain and fallacious. Adam may have recovered despite the remedy, or it may have done neither harm nor good, simply allowing nature to take its course. But this system of therapeutics was in vogue until 300 years ago. But the human mind is never satisfied with facts; it craves laws and broad, governing statements. In the search for leading principles, arose among other empiricisms, the "Doctrine of Signatures" which based the remedies for an organ on the resemblance which they bore to each other; for example, aloes in color, and faintly in outline, resembles the human liver; therefore aloes is of use in the diseases of the liver. It so happens that accidentally aloes by purging did good in liver-troubles. Therefore the disciples of this doctrine declared the principle to contain the true secret of therapeutics; and so for a time this theory prevailed in the medical world; simply because an accidental fact was confused with a consequential fact.

It will be necessary for me to waste a few words and a little time—for I consider it wasted—on the only one false doctrine which has come down to the present day. Hahnemann gave to the world three great laws on which he based all medical treatment:

1. Chronic disease is due to a certain humor in the blood, which finds its truest expression in the very prevalent disease called scabies or "itch." The invention of the microscope put to flight forever this part of his theory, by showing the small animal which is the cause of trouble in this complaint.

2. The dying doctrine of the infinitesimal dose. This idea is generally misunderstood by the laity; it is not that certain substances act in minute doses on the human system; for I could take drugs of which I need place only the smallest fragment on the tip of a knife-blade and yet they would kill. The doctrine is that substances which are inert in large quantities are all-powerful when triturated and divided into the one-thousandth or ten-thousandth part of an ordinarily small dose. For example, take chalk, which in large doses has no effect on the human organism; divide it and subdivide it until the chemist can find no trace of it and the spectrum reveals no evidence of its presence; then the true disciple of Hahnemann says chalk is all potent to cure and arrest disease. In fact it may become so powerful by subdivision that it may kill, instead of curing. Shaking the drug too much may release the latent strength to such a degree that again it may be capable of disastrous results; which may be a solace and explanation to many a homœopathic practitioner.

I remember a student I had many years ago, who complained that his family were homœopaths and were constantly tormenting him to study in that school. I said, "Why didn't you then?" "Well," he replied, "I was going to, when one day I was talking to our family physician, who was of course a homœopath, and he pulled out of his pocket a small vial and holding it up, said: 'When I began to practice medicine I put in that bottle one-quarter of a grain of mercury and filled it up with sugar of milk; as fast as the vial became empty I refilled it with sugar of milk until now it is fairly alive with the spirit of healing.' That disgusted me with homœopathy, and I came here."

3. "Similia similibus curantur." This means, that when a disease offers certain symptoms, that remedy is indicated in small

doses, which in large doses would produce a similar condition. This was not new doctrine with Hahnemann; it is as old as Hippocrates, and in its survival shows it possesses some elements of truth. But the "Father of Lies" rolls as a sweetest morsel under his tongue that falsehood, gilded with just enough truth to pass for real gold to the public.

A law of nature allows of no exceptions; if gravity draws objects to the earth at one point and repels them at another, then we can claim that the so-called law of gravitation is false and no law at all. So with this third principle of Hahnemann. If there are exceptions, it becomes no law, but merely a number of coincidences. Let us take an example, ipecac, for instance. This drug in large doses is a powerful emetic, in small doses it serves under certain conditions to quiet the stomach. The disciples of this dogma then declare "Great is homœopathy and Hahnemann is its prophet!" But let us take up the converse of this proposition "*Dissimilia dissimilibus curantur*" and use the drug opium. Now it is well known that opium in large doses deadens and subdues the stomach; given in small doses it quiets and controls in the same way the vomiting stomach; hence the disciples of this theory claim its application to everything in medicine. These are but samples taken hurriedly from the great mass of facts gathered on the subject.

In the first place symptoms are but the surface planes of disease, which mark but imperfectly the deep currents which run beneath. Let us take again the same drug, ipecac, and give it to an irritated stomach which is vomiting because of the myriad of impulses thrown out from it. Ipecac makes the symptoms worse. In the former case, the drug restored a lost tone to the organ, while in the latter case it was but fuel added to the fire. There is no law here. As I have said, it is simply a set of coincidences.

One word as to what you shall call yourselves. According to the world medicine is divided into "old school" or allopaths, homœopaths, eclectics, down to the rabble of faith-cures and Christian Science. There is no such division, and cursed be the physician who acknowledges "schools." There are but two bodies in the field of medicine—physicians and the "paths." Try to make the public understand this; if you must have some name, let it be that of a "common-sense doctor," who, brought face to face with the problem of life and death, is willing to save life in any way; who acknowledges no boundaries, no sects, no school; but who searches heaven and earth to find means to relieve suffering and cure disease.

Why homœopathy has so many followers, I have shown in an address before Yale College last spring. You will be supplied with copies possibly during the winter. Undoubtedly Hahnemann was a great benefactor to the medical profession not because of his theories, but for the accidental results which followed their application. The profession learned that disease was not always to be *fought*. Up to this time it had been treated like the seven devils of the Scriptures. It was to be cast out at any cost. The patient was bled, blistered, and purged until it grew too hot for the demon of disease to stay in the tortured body. By the action of this German theorist, who left the course of the disease practically unaffected, it was learned that a large proportion of acute sickness tends to recovery, unaided by the action of the medicinal forces called drugs. In consequence, there arose in Vienna a school of therapeutic nihilists, who believed that we have no power over disease; that it is necessary to leave everything to Nature. This was the reaction from the excessive and irrational use of drugs of the time; it had the practical import of giving the opportunity for the study of the natural history of disease.

Two important facts were brought to the attention of the profession by this Viennese school, namely,

1. That acute disease tends to recovery;
2. That it is impossible to abort its course.

Consequently you demand, What is the use or necessity of physicians in the care of such cases, if they are unable to effect the course in any way? Let me illustrate their use in acute complaints: the captain of a fast-flying ocean steamer sees in the distance over the tranquil blue water a small cloud the size of a man's hand; the mercury is falling in the barometer; and his practiced eye tells him that a cyclone is approaching. He cannot escape that storm; he cannot stay its course, but he makes taut the ship, reefs the sails, and stands ready for the blow. So with the physician; his mission is to guide his patient's course through the dangers of his sickness. He studies the ways in which the disease approaches, the methods by which it kills, and the injuries which it is apt to leave. Typhoid fever kills by

exhaustion, by high fever, by diarrhœa, by lack of digestive power due to extensive ulceration; hence here are the danger-notes for the physician. At once he puts the typhoid patient to bed, to save that strength, the last grain of which may just be sufficient to hold together the bridge which is to carry the sick man over a yawning grave. He keeps the temperature down within safe limits; for fever burns out the vital fires most quickly in this dread trouble. He secures rest at night for the sick man, to prevent the exhausting vigils in the long hours which follow midnight. In every way the leaks are stopped which are carrying off the life-blood.

The term "indication" is a most important one in all medical discourse. I will define it for you: Indication is the pointing of Nature towards relief. The diarrhœa in typhoid fever is an indication for treatment. The term goes a great ways; for it implies use not only when it is easy to see but also when it may be most obscure. It requires sagacity to read the indications in every case.

By judgment, by common sense, we learn how to use the forces called drugs in the human economy. The doctor becomes a dynamical engineer, who is to drive the most complex forces in existence, whose interplay we call "Life," and whose perturbation is sickness. To our aid we call these outside forces which fall into the arrangement which we name "Therapeutics." Hence the physiological action of remedies is the study of what they do when brought in contact with healthy organisms.

So far as it goes, therapeutics is a science, but it is by no means perfected; let us not complain; for it is my belief that it is better to live in the age when discoveries are being made, than when the world's knowledge is cut and dried. Better to live while the fruit is ripening one by one, than when it lies rotting on the ground. It is necessary to supplement pure science by empiricism, that is, the therapeutics of experience. The difference between the old and new therapeutics is this: John is given a drug in the olden times, he gets well; the credit is given to the remedy; nowadays the action of the drug is doubted, until by repeated experiments in many similar cases its value is undisputed.

Therapeutics is imperfect, more through the deficiencies of the clinician and the pathologist than from the therapeutist's faults. Take the so-called specifics; how they act is largely a problem now; but as soon as the microscopist showed us the hematozoa in the blood in intermittent fever, we showed the world how quinine acted to perfect a cure. And we stand ready to do the same when the exact nature of syphilis and rheumatism is determined, for mercury and the salicylates.

COMPOUND COMPLICATED FRACTURE OF THE SKULL: THREE CASES.

BY G. M. HAMILTON, M. D.,

ASSISTANT SURGEON, STATE HOSPITAL FOR INJURED PERSONS OF THE ANTHRACITE REGIONS OF PENNSYLVANIA.

Case 1. S. S., a miner, 21 years old, was admitted June 26, with a compound, complicated fracture of the skull, caused by a heavy fall of coal in the mines. The fracture extended from above and to the right of the occipital protuberance across the median line below. There was so much compression that it was not necessary to anæsthetize the patient for the operation of trephining. After the fragments were removed, there was an opening in the skull, one and one-half inches wide by two and one-half long, through which the lacerated membranes and brain could be thoroughly inspected and cleansed. The dura-mater had been detached from the bone, in the vicinity of the wound, by the force of the blow, and portions of the patient's hat, small pieces of coal and other foreign matter had been forced down between the membrane and bone. These substances were carefully removed, good drainage was provided, the wound closed, and a bichloride dressing was applied. All signs of compression disappeared in a few hours. On the third day the temperature was 100.4°; but it soon began to decline, and three days later it was normal. The patient was discharged July 31, and is now again at work in the mines.

Case 2. W. H., of Ashland, 16 years old, was brought to the hospital on the night of July 3, with a compound, complicated fracture of the skull, the result of the explosion of a "gas-pipe cannon." The wound in the soft structures extended transversely across the forehead, immediately above the supra-orbital ridge, from the median line to

within an inch of the right ear. The bone was fractured through the frontal sinus, both the outer and inner walls being crushed and driven in upon the membranes, which together with the brain were extensively lacerated. The trephine was applied and fragments of bone and injured brain matter were removed, the wound sutured and dressed with the usual antiseptic precautions. On the morning of the second day, the temperature was 102°. Upon examination of the wound, the drainage-tube was found to be occluded by a further separation of brain tissue, and the skin to be somewhat tense from retained wound secretions. A new drainage-tube was substituted and the temperature almost immediately began to decline, reaching normal the morning of sixth day. This patient was discharged August 24.

Case 3. L. B., a miner, 22 years old, admitted July 6, with compound complicated fracture of the skull, involving the temporal and adjoining portions of the parietal, sphenoid, and occipital bones on the left side. This injury was also caused by a fall of coal. The patient when admitted had very grave symptoms of compression, and to relieve this, it was necessary to remove the greater part of the temporal bone—that portion only being left which contains the carotid canal. The membranes and brain were greatly injured, but the most dangerous complication was a wound of the lateral sinus, near the point where it terminates in the internal jugular vein. The fragments of bone were wedged in in such a manner as to prevent fatal hemorrhage at the time of the accident. When they were removed, the hemorrhage became so profuse as to threaten immediate death of the patient; but it was controlled by means of a graduated aseptic compress. This compress was removed at the end of seventy-two hours, and the wound was allowed to granulate. The patient is now walking about the hospital almost well enough to be discharged. On account of the removal of the temporal bone, there is, of course, permanent paralysis of the muscles supplied by the seventh nerve and complete loss of hearing on the injured side.

These three cases represent a class of fractures treated in large numbers at this institution, and the good results obtained are mainly due, in my opinion, to the operative treatment at the time of admission; to the free use of the trephine and elevator; and, of course, to a strict adherence to the principles of antiseptic surgery. Sometimes, it is true, the fragments can be removed by means of the elevator alone, but even in these cases, Dr. Biddle considers it good, and if there is injury to the membranes and brain, necessary treatment—where it can be done—to enlarge the opening in every direction until he has a solid margin all around, with healthy membrane attached beneath. This gives a chance for free drainage and reduces to a minimum the dangers of secretions becoming diffused between the membrane and the bone. No matter how large an opening is made, all bone that is likely to become a source of irritation must be removed, and the sooner it is done, the better will be the chances of recovery.

The cases just reported were operated upon in this manner by Dr. Biddle, assisted by Dr. C. A. Dundore and myself, and in none did there develop any symptoms of meningitis, other than of strictly local character. The comparatively high temperature of *Case 2* was not due to meningitis, but to the retained secretions, as was proven by the rapid fall after re-establishing drainage.

OBSERVATIONS ON THE THERAPEUTICAL EFFECT OF THE VIOLET END OF THE SPECTRUM ON VISION.[1]

BY G. LINDSAY JOHNSON, M. A., B. S., F. R. C. S.,

LONDON, ENGLAND.

In a case of retinitis accompanied by partial retinal detachment in which I had prescribed the constant use of blue glasses, I noticed an evident increase in the visual field and a corresponding improvement in vision, it occurred to me that if this improvement in vision was caused by a blue glass, which admitted more or less of the red end of the spectrum because fitted to frames which allowed a considerable amount of daylight to reach the eye, the uninterrupted and exclusive action of the blue end of the spectrum might produce a more favorable result still. After examining and preparing a very large

[1] Abstract of paper read at the Opthalmological Section of the Leeds meeting of the British Medical Association. Prepared for the MEDICAL AND SURGICAL REPORTER by the author.

number of colored glasses and solutions, I succeeded in obtaining a glass which absorbed all the spectrum except the red and a portion of the orange, as well as one which cut off all the red, orange and yellow rays to within ten degrees of the E line. This latter I termed "Spectrum blue," being the nearest approach to a theoretical blue that I could get by art, while the former I call "Spectrum red." Previous to obtaining the spectrum blue glass I devised a pair of goggles, in which the glass was replaced by a trough made by fitting two thin circular plates of glass into a ring and having their surfaces parallel and at 3½ millimeters apart. This trough was filled with a solution of ammonio-sulphate of copper. This form of glass had to be abandoned, however, owing to the bleaching action of light on the solution. The spectrum blue glass above mentioned, on the other hand, formed a perfect substitute.

Carefully worked pieces of this glass were fitted into spectacle frame goggles which fit so close around the orbit that no light could possibly enter which did not pass through the glass. For ventilation the sides of the cups were made of two thicknesses of finest wire gauze, enclosing one of fine crape. The patients were instructed to fit on the spectacles the instant they awoke in the morning, after bathing the eyes and before putting up the blind, and to refrain from removing them until they retired to rest at night.

During the past three years a great number of patients have been treated with the spectrum blue glasses in the above way. Of the various eye diseases so treated, detached retina, optic neuritis and neuro-retinitis afforded the most satisfactory results. In nearly every case of detached retina the field of vision was largely increased, although in only four cases out of about thirty treated was the retina actually seen to have returned to its position. In every case of neuro-retinitis due to temporary causes the vision returned rapidly after a few days, although in some cases the vision had been declining or stationary for weeks previously. I find that cases which can be benefited by the use of the glasses show improvement as a rule within three days, and if no improvement shows itself at the end of a week, none may be expected. Very few cases of relapse in detached retina have been noticed, even after the glasses have been ultimately discontinued.

Reports of Clinics.

BELLEVUE HOSPITAL.

MEDICAL CLINIC—PROF. A. L. LOOMIS.

October 15, 1889.

Typhoid Fever.

The first patient shown by Dr. Loomis was a man 24 years old, in perfect health up to 8 days ago, when he was suddenly attacked with six or seven chills, fever, headache and vomiting. The day before this, he was at work and suffered from no malaise or diarrhœa or headache. The first day of his illness he acknowledges some looseness of the bowels, but he declares they have been regular since. He has been getting sicker and weaker from day to day, and finding that he was not likely to improve at home, he entered the Hospital yesterday. He was found to be quite deaf, probably from large doses of quinine. He still complains of slight headache and dimness of vision.

His temperature on admission was 100°; it went up in the afternoon to 103°, and in the evening to 104⅕°; later it was 103½°, and later 104⅖°. To-day it has varied from 104° to 103⅘°—a pretty steady temperature of 104°.

Dr. Loomis then said: "From this history can we make a diagnosis? We can—of typhoid or remittent fever. But does typhoid begin in the sudden manner and with severe and repeated chills? Occasionally; but not as a rule. And is the sudden rise of temperature noted yesterday typical of this fever? The German and the English writers lay great stress on a typical fever curve in typhoid fever as it is observed by them, but here in this country we observe it but occasionally. As a rule during the first week the temperature goes up and down suddenly several times, but with a steady rise withal; and during the second week it is usually about stationary. This temperature of 104° is not very high—would represent, perhaps, an average case. A stationary temperature can occur too in remittent fever: this usually takes place during, or later than, the third week, however."

Examining the patient, Dr. Loomis found his face flushed and not of the dark mahogany color of typhus, or having the bright red spot often seen in typhoid. There was

sordes on the lips and teeth and tongue, which is dry and brown as well.

The patient had also difficulty in protruding his tongue and also his acuteness of perception was apparently dulled. His pulse was 86 and of good quality. On the abdomen there was a profuse typical eruption, most of which appeared the day before, a few spots the day before and some this day. There was no distention, no tympanites, no tenderness and no pain in iliac fossa. There was gurgling, but this, Dr. Loomis said, is a symptom associated with many other conditions, and hence by itself of little diagnostic value. This absence of abdominal signs, however, should be looked upon as a good sign for the patient. It shows that, so far at any rate, the intestinal lesions are not severe and the dangers to the patient from complications from this source are very much lessened. The record shows that the patient had had two stools since his admission to the Hospital and that they were loose and light colored. The eruption, however, made the diagnosis positive, and it was needless to hunt for further confirmation, as it does not occur in any other disease. This was not a severe case, though it was yet too early in the disease to say that it will not prove to be one.

The treatment employed was milk diet and bismuth. Dr. Loomis believed this drug to be practically inert, and, as it is necessary to give something, it answers the purpose very well here. He had also applied the cold coil upon the abdomen. This will frequently reduce the temperature one or two degrees. There is no danger, however, from the present temperature of this man. It is but the expression of his disease, and as long as it remains where it is, nothing further will be done to reduce it.

Referring to cold baths and cold applications, Dr. Loomis said they had the sanction of the German, many of the French and some English authorities, and their reasoning and apparent results are very fascinating. He had tried them. He had used the bath slowly reduced to 65° until the patient's temperature had fallen three or four degrees; and repeated the procedure when the temperature became high again; but his experience, statistics and careful observations are against the use of the cold bath. He would not say he had killed patients by this method; but the fact remains, that they died; and he believed they did not do so well as those who had absolutely no treatment, in the manner of antipyreties. He does not believe these objections always applicable to the wet pack and cold sponging, and often uses these, provided they do not depress the heart or hurry the respiration, and do control the temperature for an appreciable time. But any procedure that will cause a small, fluttering, weak pulse, and increased effort in breathing must necessarily do harm.

In a simple case the chief care of the physician should be, to see his patient twice a day and watch for the appearance of complications; then not to drug him; and finally not to overfeed him. As a rule one quart of milk a day will be better than three. If the quantity is excessive it is undigested and it increases the diarrhœa.

Acute Bright's Disease.

The second case was one of a man, 36 years old; a drinking man, and a hard worker; who had been exposed to the weather by his occupation, which is that of a boatman. Three weeks ago, after a debauch, he discovered a swelling of his penis and scrotum, which came on suddenly. There was also difficulty in voiding his urine, which was of dark color and scanty—less than a pint in twenty-four hours. There was vomiting and some diarrhœa, but no headache, or disturbance of vision or pain in the back. On the following day his feet and legs began to swell, and, the vomiting continuing and his condition growing worse, he entered the Hospital ten days ago.

Examination showed well marked œdema of legs, and also of the scrotum and penis; some of the face, and some of the abdomen. The abdomen showed also enlarged veins. Both lobes of the liver were markedly increased in size. The spleen was somewhat enlarged, and the heart's apex was one inch to the left of the nipple. The first sound was indistinct and the area of dulness increased. There was a murmur at the base with the first sound, too rough to be anemic, which was observed on the day of the patient's admission. The pulse showed a very high arterial tension. Examining the lungs Dr. Loomis found behind and below feeble respiration and râles of œdema. The urine had a specific gravity of 1.025. It was slightly acid and precipitated half its bulk of albumin. It contained blood, and hyaline, epithelial, granular and blood casts.

This patient, Dr. Loomis said, was suffer-

ing with acute Bright's disease, with the first stage of cirrhosis of the liver, and probably an old heart lesion. The important question was, whether, considering the condition of the heart, the arterial tension, and the slight improvement that the patient showed from treatment the acute inflammation be not grafted upon an old kidney lesion.

PERISCOPE.

The Acids of the Stomach.

There is no doubt that the chief acid found in the stomach during natural digestion is free hydrochloric acid. This has been abundantly proved by Bidder and Schmidt, and by numerous observers succeeding them. The methods used are, however, too long and too complicated to employ in clinical work. The physician wishes to know what, in a particular case of disease, are the chemical changes going on in the stomach; whether, for example, hydrochloric acid is present as well as pepsin and organic acids. Now, in the examination of the contents of a diseased stomach, three forms of acid may be present—hydrochloric acid, a mineral acid; organic acids, such as lactic acid, butyric, etc.; and thirdly, acid phosphates. It is chiefly of importance to determine the presence of hydrochloric acid and of organic acids. Many methods have been proposed for doing this; they consist mainly in testing the effect of the stomach contents on various colored solutions. Thus a solution of methyl-violet is decolorized by hydrochloric acid, so that if this reaction is obtained the free acid is present in the liquid tested. Lactic acid turns the violet a dirty yellow. Tropæolin also is turned deep reddish-brown by free hydrochloric acid. Unfortunately these tests, simple as they appear, are not accurate, since the reactions are interfered with by the presence of peptones and of some neutral salts, and, as these are usually present in the stomach contents, no reliable results can be obtained by using methyl-violet and tropæolin. They have been superseded by Congo red, which is turned blue by free hydrochloric acid, and by a solution of vanillin and phloroglucin in alcohol, which is turned a deep red by the same acid. These simple clinical tests are, however, rendered useless by the fact that they are interfered with by the presence of peptone, ammonium salts, chlorides, and phosphates.

In the present state of our knowledge, therefore, there is no reliable indicator for the presence of free hydrochloric acid in the stomach contents. Other methods which may be used are too complicated for clinical use. Thus ether has the property of dissolving organic acids from a liquid, leaving the mineral acids in solution. It may thus be used for separating the lactic, butyric, and other acids from the hydrochloric acid; and if in a liquid obtained from the stomach it is found that ether removes the whole of the acids present, it may be concluded that no free hydrochloric acid is present. In many cases this conclusion would be an important one as a clear indication for a line of treatment. Dr. Leo has lately published a new method for the indication of free hydrochloric acid which may prove useful. Leo considers the case where it is only a question of the presence of free hydric chloride and of an acid phosphate. To a few drops of the stomach contents a pinch of carbonate of calcium is added; if the acidity, as tested by litmus paper, disappears, only a free acid is present, but if the liquid is still acid after the addition of the chalk, an acid salt is present. If, moreover, organic acids be present they must be first removed by shaking with ether before the chalk is added. It does not seem that Leo's method is one that can be applied at the bedside, because the detection of free hydrochloric acid is chiefly requisite in those cases in which organic acids are also present, as in cases of dilated stomach. At present, indeed, a ready method, suitable in clinical practice for the detection of free hydrochloric acid in organic liquids, is a desideratum.—*British Med. Journal,* Oct. 5, 1889.

Anæsthesia.

The subjects of selection and methods of use of anæsthetics, the danger of anæsthesia, and the treatment of the accidents which occur during it, have been so much discussed, indeed, so hackneyed, that we almost feel like apologizing for alluding to it. The matter is one, however, of the greatest importance, and the reporter of a case of death from ether, in the *New York Medical Journal* of May 18, held that the knowledge of physiological therapeutics has not yet been thoroughly diffused through the rank and file of the profession. In this case a

middle-aged Frenchman, who had been suffering from tubercular disease, with albuminous urine, and aortic and mitral systolic murmurs and feeble heart-sounds, was given ether with the intention of the performance of Syme's amputation. A few moments after etherization was commenced the respiration faltered, and the patient became deeply cyanosed. This somewhat alarming condition quickly passed away, and five minutes later the assistant having the pulse under observation suddenly announced that it had ceased. "Immediately hypodermic injections of brandy, ether, and sulphate of atropine were given; amyl nitrite was applied to the nostrils, artificial respiration was practised, and the head and shoulders were depressed by elevation of the foot of the table; but all was in vain; the patient was dead."

According to the surgeon in charge who reports the case, the death was the result of syncope, and largely the outcome of the diseased condition of the heart, which was found at the autopsy to have a completely adherent pericardium, atheroma of the aorta, and stenotic mitral valve. The kidneys were also in a condition of advanced contraction.

In the first place, it is essential that a case like this be not allowed to go upon record as one of death due to ether. We doubt very much the wisdom of attempting a severe surgical operation like amputation of the foot in a man who has disease of the kidneys, disease of the mitral and aortic valves, and the other numerous organic ills which affected this Frenchman. If an operation was justifiable at all in such a case, both the surgeon and patient should appreciate the excessive risks, and no therapeutist should charge the death against the anæsthetic. The peculiar greatness of the danger in the case becomes manifest when the selection of the anæsthetic is thought of. The condition of the kidneys strongly contraindicated the use of ether; the clinical evidence which we now have being enough to demonstrate that chloroform is safer than ether in cases of renal disease, unless the heart-muscle has undergone secondary degeneration. This is probably because the amount of chloroform required to produce anæsthesia is so much smaller than that of ether that less strain is thrown upon the organ that eliminates it, hence the diseased kidneys are less irritated by chloroform than by ether. On the other hand, in the case under consideration the condition of the heart evidently contraindicated the use of chloroform; in fact, both ether and chloroform were contraindicated, and nothing but the gravest necessity could justify their use.

It is especially, however, to the treatment employed that we want to call attention, and we have no hesitation in affirming that if the patient had any chance of recovery at all, such chance was destroyed by the methods used for his relief. Suppose a doctor, having a case of opium-poisoning to deal with, were, for the purpose of relief, to administer morphine hypodermically, what would be the judgment of the profession as to the method? Evidently that it was a madness. But here we are told that hypodermic injections of ether and brandy were given. Probably almost every one in the profession would agree with us in believing that the use of hypodermic injections of ether was improper; possibly only a minority would agree to the statement that the administration of the brandy was almost, if not quite, as dangerous. Ether and alcohol, are, however, chemically almost identical; physically, except in the matter of volatility, they are exceedingly alike, and in their relations to the human organism they seem to differ only in so far as one is more volatile, and therefore more quick and more fugacious in its action than the other. Each primarily stimulates and secondarily depresses the heart, and we believe that in accidents of etherization the administration of alcohol is equivalent to the administration of more of the poisonous agent. This conclusion rests also not simply upon *a priori* argument. As long ago as 1883, R. Dubois, in a series of experiments made upon the lower animals, found that the free administration of alcohol intensifies the influence of chloroform and lessens the minimum fatal dose. Certainly alcohol and ether are more nearly equivalent remedies than are alcohol and chloroform.—*Therapeutic Gazette*, July, 1889.

Protection of the Health and Life of Infants.

Landouzy and H. Napias state, in a communication in the *Bulletin Médical*, September 4, 1889, that the mortality among children is frightful in every country, especially in the first twelve months of life; it may reach, in this period, as high as 34 per cent., or more than one-third. To remedy this we must know the complex

causes of the mortality. They offered the following propositions for consideration by the Congress on Hygiene which met in Paris last summer. 1. In all countries a uniform method should be adopted for recording the statistics of mortality in infants. These statistics should follow the history of children from year to year, from birth up to the fifth year. 2. The registration of the deaths of children should be made only after a vigorous investigation covering the following points: The nature of the disease which has caused death; the exact date of birth; the method of feeding; by the breast or bottle, or both, or on other kinds of nourishment; the character of the milk; the transmissible diseases which may have affected the parents or care-takers; and the healthfulness of the lodgings occupied by the parents or nurses. 3. Every legal measure, administrative or private, which will favor the nursing of children by their mothers, will promote the hygiene of children. Artificial feeding is the surest of all the means of contagion for infectious diseases. This explains why bringing up children exclusively on the breast gives them—all things being equal—a good chance of surviving. In cases in which nursing by the mother is impossible, that mode of artificial feeding should be encouraged which will give the greatest guarantee against the transmission of morbid germs; a bottle should be chosen, and all measures adopted to assure the non-contamination of the milk. 4. It is expedient that proper notions of infantile hygiene should be spread abroad by all possible agencies, in the cities and in the country; they should be imparted to girls in the primary school; and in the large cities especially should there be annexed to the primary schools day nurseries in which young girls, in the last two years of schooling, could take practical care of infants. 5. In industrial cities every measure taken to diminish the working hours of women in the shops and factories will be a hygienic measure of which children will naturally reap the benefit.

Beta Vulgaris for Habitual Constipation and Hemorrhoids.

Dr. S. Kazatchkoff states, in a communication to *Meditzina*, No. 6, 1889, that the common beet is a popular remedy in central Russia to overcome atonic constipation and hemorrhoids. It is given in the form of a decoction, in doses of a half-cup to a cupful daily; it is said to cause neither colic nor digestive disturbances, nor to be followed by constipation. The patient, however, becomes accustomed to the remedy after using it a week, and the dose has to be increased. Nevertheless, Kazatchkoff attributes to it greater virtues than to castor oil, rhubarb, magnesia, podophyllum, and to the mineral water purgatives.—*Gazette Hebdomadaire*, September 27, 1889.

Treatment of Purpura Hemorrhagica with Nitrate of Silver.

Dr. Poulet has a communication on the treatment of purpura hemorrhagica with nitrate of silver, in the *Bull. gén. de Thérap.*, May 30, 1889. The author relates two characteristic and severe cases of purpura hemorrhagica, which promptly recovered when nitrate of silver was given internally. The first was that of a boy, 12 years of age, with a family history of tuberculosis and albuminuria, who, eight days previously, had been attacked by a petechial eruption, culminating in profuse epistaxis, which rapidly reduced him to a bloodless condition. Poulet ordered tincture of the chloride of iron and the acid infusion of roses, and, as this did not check the hemorrhagic tendency, he followed it up on the following day by plugging the nostrils and giving subcutaneous injections of ergotine. The bleeding, however, continued as before, and the condition of the patient became critical. He then resorted to nitrate of silver, in doses of one-fifth of a grain, twice a day, incorporated with bread-crumb and given after food. The next day a manifest improvement had taken place, and in the course of three or four days the drug could be discontinued. The lad gradually recovered, but the loss of blood had been so abundant that it was years before he ceased to be delicate and anemic. The second case was that of a young woman 20 years old. Eight days after her last menstrual period purpuric spots made their appearance, with frequent attacks of bleeding from the nose, stomach, and bowels. She was fairly well nourished, and lived in the open country. Her previous health had been good, but for some weeks past she had experienced a feeling of lassitude, with loss of appetite. The eruption was most marked at first on the lower extremities, but soon

became general. Various anti-hemorrhagic remedies were tried, but without any marked effect on the bleeding. There was slight albuminuria; legs a little puffy. Under these circumstances he ordered one-eighth of a grain of nitrate of silver in a pill, three times a day. The effect was so marked that within four days sight and hearing were restored, and the purpuric patches began to fade. The hemorrhages ceased after the first day of the exhibition of the nitrate. Twelve pills in all were taken, and they sufficed to effect a cure.—*London Medical Recorder*, June 20, 1889.

Pea-Soup as a Substitute for Beef-Tea.

Dr. Ris of Kloten, Switzerland, says *The British Medical Journal* of Sept. 28, emphatically recommends pea-soup as an excellent substitute for beef-tea for invalids, convalescents, and more especially for patients suffering from cancer of the stomach, or *diabetes mellitus*. Take peas, water, and sufficient amount of some vegetable suitable for soup, and one-half per cent. of carbonate of soda, and boil the whole until the peas are completely disintegrated; then let the soup stand until sedimentation is complete, and decant the fairly clear, thin fluid above the deposit. The product is stated to resemble a good meat-soup in its taste, to be at least equally digestible, and at the same time to surpass the very best meat-soup in nutritive value. The latter statement may appear surprising, but the author reminds us that peas (as well as beans or lentils, either of which may be used instead of peas) contain a considerable portion of legumen; that is, a vegetable albumin which is easily soluble in a faintly alkaline water, is not coagulated by heat, is easily absorbed, and equal to the albumin of eggs in its nutritiousness. —*Science*, Oct. 18, 1889.

The Treatment of Abdominal Aneurism.

A novel procedure was attempted by Mr. Keetley in a case of large abdominal aneurism under his care at the West London Hospital. The tumor, which mainly occupies the epigastric region, and projects prominently forwards, had thrust the liver into the right lumbar region, and Mr. Keetley, in order to control if possible the pulsation in the aneurism, devised and carried out the following procedure: An incision was made below the ribs on the right side, and the peritoneal cavity opened; a specially constructed instrument with a handle, a curved stem, and a thickened extremity was then passed into the wound and through the foramen of Winslow, between the liver and the tumor, and made to compress the aorta above the origin of the cœliac axis. Upon the first occasion the stem was of copper, and unfortunately bent under the pressure to which it was subjected. The operation was repeated with an instrument constructed of steel. It was found that the object aimed at could be obtained, but not entirely. Although the aorta was by this means partly compressed, it was not possible to control the circulation sufficiently to render it justifiable to continue the attempt. However, Mr. Keetley is satisfied with the feasibility and the ultimate utility of the procedure, and its non-success in the present instance is doubtless largely due to the immense size of the tumor preventing even the fingers from reaching the aorta above the disease, and disturbing the normal relations of the parts. —*Medical Press and Circular*, June 12, 1889.

Thirty Years in a Man's Body.

Dr. Nisson relates, in the *Magdeburger Zeitung*, the following case which has come under his observation: "I have just extracted," he says, "from the arm of a patient of mine, an iron-founder, a darning needle seven centimetres long, which was embedded in a muscle (the *triceps brachii*). The needle was completely black from oxidation, and had for years caused great pain to the patient, who was supposed to suffer from rheumatism in various parts of the body, and had been treated for that disease by numerous doctors without success. As the man has no recollection of a needle running in him, it is probable that it must have done so in his early childhood, and that it had been traveling about his body for some thirty years before it was discovered. It is worthy of note that when he was two years old he was treated for some months for disease of the spine, the appearance of which disease may have been caused by the presence of the needle in the neighborhood of the spine, and the irritation consequently set up."—Philadelphia *Ledger*, Oct. 19, 1889.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

ANÆSTHETICS AND ACCIDENTS.

A few weeks ago a well-known citizen of Philadelphia, in the prime of life, died suddenly after having been anæsthetized with nitrous oxide gas in order to have a tooth extracted painlessly. He did not die while under the anæsthetic; but, soon after he recovered consciousness, he had symptoms of apoplexy, which increased until he died, after a lapse of a few hours. He was a man of large frame, of excellent general health and vigor, and of unexceptionable habits of life. The Coroner's investigation which followed did not include an autopsy, and so the immediate cause of death was not certainly known, but the diagnosis of apoplexy seems to have been justifiable.

This is an extraordinary case—and fortunately a very rare one—of death following soon after anæsthesia with nitrous oxide gas. No one, we believe, has asserted that in this case the anæsthetic directly caused death, and the general opinion seems to be that it was a mere coincidence. This opinion we cannot agree with unconditionally; for we cannot but believe the condition of nitrous oxide anæsthesia started the train of changes which culminated in apoplexy—if this was really the immediate cause of death.

Still, it may be said that accidents following anæsthesia with nitrous oxide gas are almost as rare as phœnixes, and scarcely to be named in contrast with its beneficent effects. The same may be said of ether and chloroform; although in their case danger and death are by no means uncommon.

Justice to the truth requires that all the circumstances attending a case of death during or soon after anæsthesia should be known and duly estimated before deciding in how much the result is fairly chargeable to the anæsthetic. In a case reported in the *British Med. Journal*, Oct. 5, 1889, a woman in Birmingham, twenty-five years old, of very nervous and excitable temperament, desired to have some teeth extracted, and insisted upon being anæsthetized. In the presence of her husband and the dentist, her medical attendant administered chloroform. The patient was seated in an easy chair, and, after inhaling a few breaths of chloroform, she slipped down in the chair, and her pulse and breathing stopped. Artificial respiration was at once resorted to, but without success. It seems perfectly clear that the patient was not anæsthetized when she died, as she had only just commenced to inhale the chloroform, and, of course, no attempt had been made to extract her teeth. The Coroner's jury returned a verdict that death was due to syncope, and that no blame whatever attached to the administrator. In commenting on this case, our British contemporary very truly says that it is well known that syncope may result from violent emotion, and especially from the effects of fear. It repeats the story of a case recorded in Germany a few years

ago in which a female patient visited a dentist, and requested him to extract some carious teeth, demanding, at the same time, that she should be chloroformed. The dentist explained the risks of chloroform, and suggested nitrous oxide gas; but his patient persisted, and he pretended to humor her. Having, however, a wholesome dread of chloroform, he substituted Cologne water, and bade her inhale the supposed anæsthetic from a folded towel. After two or three inspirations she suddenly fell from the chair, and died.

Such stories as this indicate that it would be but hasty and ill-considered judgment to look no further than to the anæsthetic to explain deaths which at first sight might seem chargeable to it. They indicate at the same time dangers connected with the administration of anæsthetics which are all the more serious because they are rarely encountered, and perhaps never anticipated. Due consideration of them, therefore, may serve a double purpose—in diminishing, as well as defining, the elements of real danger in anæsthesia.

CHLORALAMIDE, THE NEW HYPNOTIC.

Several recent papers upon the new hypnotic, chloralamide, make it possible to give briefly its more important properties and effects. It is formed by the addition of chloral anhydride to formamide, and is found as colorless crystals, having a slightly bitter but not disagreeable taste. According to Drs. Hagen and Hüfler, in a communication to the *Münchener med. Wochenschrift*, No. 30, 1889, the effect of the drug begins in about one-half hour after its administration. In most cases thirty grains are sufficient for a dose, but forty-five grains may be given without hesitation. Hagen and Hüfler give notes of twenty-five cases in which chloralamide was employed; in most of these the patients were suffering with grave organic diseases. A hypnotic effect occurred in twenty of the patients, and in sixteen it was perfect. The remedy failed to act only in the case of a paralytic, and in a patient strongly consumptive. The sleep produced is described as quiet. Only eight of the patients complained of slight headache on awaking, while the rest felt entirely well. Patients do not appear to become accustomed to the drug readily; for it is stated that, when frequently employed in the same patient, its good effects continued, and no disagreeable secondary effects were seen. It is noteworthy that the remedy also acted well when the sleeplessness was due to violent pain, and that the healthy patients, who were given it in the morning without anything being said to them, slept the whole day with short interruptions, and also enjoyed their usual good sleep the following night.

Dr. Eduard Reichmann, in a paper published in the *Deutsche med. Wochenschrift*, No. 31, 1889, confirms the experience of the authors just quoted in a very satisfactory manner. As regards the dose, he states that fifteen grains was uncertain in its effects, but that thirty grains was nearly always successful. Reichmann makes the highly important statement that he observed the behavior of the pulse especially, and that chloralamide exerted no recognizable influence upon the heart and vascular system—in agreeable contrast, therefore, with the effect of chloral.

The experience of Erich Peiper (*Deutsche med. Wochenschrift*, No. 32, 1889), is also in the main confirmatory of that of the other experimenters referred to. Disagreeable symptoms, however, consisting of headache, dizziness and weariness, were observed by him somewhat more frequently. Peiper nevertheless prefers chloralamide to chloral.

Finally, Dr. Rabow has a short communication on chloralamide in the *Centralblatt für Nervenheilkunde*, No. 15, 1889. He also reports good results from the new remedy; in nervous sleeplessness and in the sleeplessness of alcoholics, somewhat larger doses—sixty grains—were employed. In

excited and maniacal patients, however, it did not act.

Many new hypnotics have been offered to the profession in recent years. Most of them are useful under special circumstances, and almost all are found sooner or later to have peculiar disadvantages. Perhaps the attitude of the practitioner should be to try all, and to "hold fast to that which is good." The present hypnotic, chloralamide, appears to have certain advantages. It is cheap, the dose is small, it may be given in capsules or in solution, and its taste is said not to be disagreeable. If given in solution the water should not be too warm—not over 140° Fahr.—as otherwise the chloralamide is decomposed and becomes inactive. It is to be hoped that later experience will substantiate that already given, especially with regard to the harmlessness of the remedy.

OPERATIONS FOR GOITRE.

It is not many years since operations upon the enlarged thyroid gland were regarded with well-founded dread by almost all surgeons. The dangers of cutting operations for goitre were so great and the mortality so large that little was done for the relief of this disfiguring and distressing disorder beside injecting the tumor with iodine or occasionally some other so-called absorbent. This condition has been changed, largely through the persistent devotion of Kocher, of Bern, who has for some years steadily studied and practised operations upon the thyroid gland. The result of this work is shown in a report on 250 operations published originally in the *Correspondenz-Blatt für Schweizè Aertzte*, and summarized in the *Memorabilien*, September 13, 1889. The report covers five years and a half of Kocher's experience, and presents results worthy of the most careful attention.

In the first place—as Dr. Betz points out—it appears that in Kocher's hands the statistics of extirpation of the thyroid have become so favorable that its mortality is no longer a serious feature. In only six of Kocher's two hundred and fifty extirpations did death follow—that is, in only 2.4 per cent.; while in three of the fatal cases the disease was malignant, and one was a case of Graves' disease. If these cases be eliminated from the total, the mortality is reduced to *eight-tenths of one per cent.* Even this result appears in a more favorable light when one learns that, in one of the remaining fatal cases, the patient was probably poisoned with ethylene, while the other patient was brought to the clinic almost moribund, in extreme dyspnœa.

In the main, Kocher adheres to the method associated with his name. The Winkel curved incision is preferred for difficult cases and when the thyroid is large; while for simpler tumors the oblique incision at the anterior border of the sterno-cleido-mastoid muscle, with a preference for the transverse incision, which does not give as good access to the field of operation, but from a cosmetic point of view is said to give the most beautiful results. The recurrent laryngeal nerve, and the principal trunk and the branches of the sympathetic, are most likely to be wounded. Tying the inferior thyroid artery must be done with the greatest care. In regard to later results of extirpation of the thyroid, it seems that what was once known as *cachexia strumipriva* might be more correctly called "*cachexia thyreopriva*," and it seems important that in every extirpation of the thyroid gland some portion shall be left behind. Kocher, who is the best judge of such matters in the world, says that extirpation of the thyroid is indicated, first, in malignant disease if the disease is not diffuse, and also in cases in which there is a well-founded suspicion of malignancy; second, in inflamed thyroids which are free from cysts; third, in diffuse so-called hypertrophies. The contra-indication to extirpation is the absence of healthy gland substance upon the other side.

Enucleation is indicated, first, in cystic thyroids—that is to say, in cases in which cysts form the principal part of the tumor;

second, where there are large isolated nodules imbedded in relatively sound glandular tissue; third, in immovable thyroids containing large nodules.

Scraping out (*évidement*) is indicated, first, where there are isolated nodules of soft consistence in relatively sound gland tissue; second, in cases such as those noted under the indications for enucleation, if there are nodules of soft consistence and with free and numerous vascular connections in the neighborhood.

Resection (partial excision) of the thyroid takes the place of extirpation and enucleation in the numerous cases which do not sharply correspond to the above indications. Ligation of the thyroid arteries should be performed in vascular thyroids, especially in Graves' disease.

Taken as a whole, we can heartily commend to the notice of our readers the views of Kocher on this important subject. No place in the world affords such full opportunities of studying it as he enjoys, and his wonderful success gives his opinions a weight which cannot attach to those of any operator less experienced and less successful.

CARBONIC ACID IN PULMONARY CONSUMPTION.

It is a well-known fact that diabetes and pulmonary consumption are very intimately associated, the one with the other; and, according to Ebstein, the carbonic acid production is markedly lessened in quantity in the former disease. Animated by the belief that the partial absence of carbonic acid is conducive to the growth of the tubercle bacilli, and that this anomaly sustains a causative relation to phthisis, Dr. Hugo Weber advocates the administration of this gas in the treatment of this disease in the *Berliner klin. Wochenschrift*, Sept. 2, 1889. He gives one teaspoonful of sodium bicarbonate before each meal, immediately after a glass of water containing twelve drops of muriatic acid has been taken. About half a pint of gas is generated by this procedure which is believed to be exhaled through the lungs, and to have a germicidal influence on the tubercle bacillus.

He reports ten cases of consumptives subjected to this plan of treatment, and it is encouraging to learn that all derived benefit —even those in whom the destructive processes in the lungs had advanced to an extreme degree. It is especially noticeable that the improvement took place while the patients remained in the same general conditions to which they had been subject before—that is, they were not taken to hospitals or treated in any way which could throw doubt upon the part in their improvement from Dr. Weber's method.

UTERINE DISPLACEMENT AND PREGNANCY.

It is generally believed that retroflexion and retroversion of the uterus predispose to sterility by reason of the failure of the spermatic fluid to enter the displaced os and cervix, and that, when pregnancy does occur, it very soon becomes complicated by the incarceration of the enlarging uterus. New light has been thrown upon this subject by recent investigations by Professor Martin, of Berlin, who found in the records of his clinic in Berlin, 121 cases of persistent retroflexion of the pregnant uterus in a total of 24,000 patients. In 27 of these cases the deformity of the uterus was congenital, and was complicated with endometritis and by affections of the tubes and ovaries; but even under these unfavorable circumstances, conception occurred. Even gonorrhœal infection, so commonly believed to cause sterility, failed in one case to prevent conception, although accompanied by retroflexion. Martin draws the very practical conclusion that it is not the uterine deformity, but a coincident catarrhal or inflammatory state of the endometrium or tubes, which causes sterility in these cases. Congenital retroflexion alone does not prevent conception.

The usual belief that pregnancy and parturition correct uterine deformity was disproven by ninety-four cases, in which repeated pregnancy failed to remove it: nine of these patients had been under treatment for misplacement and were wearing pessaries when conception occurred. A ready explanation of the fact that the family physician meets so few cases of pregnancy in persistently retroflexed or retroverted uteri arises from the frequent occurrence of spontaneous reposition. As the womb enlarges nature lifts it above the pelvic brim in nearly all cases. The most common symptom, warning the attendant that such is not the case, is frequent and difficult urination, for which he finds no other cause. This should lead to careful examination, and to efforts at reposition in the knee-chest position. Should irreducible incarceration result, spontaneous or induced abortion may solve the problem. But this failing, and the womb remaining fixed, this organ may be removed through the vagina if small, or amputated above the pubes, as in the Porro operation. Martin's article in the *Deutsche Medecinische Wochenschrift*, Sept. 26, 1889, and a case reported by Sperber in the *Centralblatt für Gynäkalogie*, No. 36, 1889, and a method of reposition described by Cohnstein, in the *Archiv für Gynäkologie*, Band XXXIII, Heft 1, furnish interesting recent literature on this subject to those who may wish to pursue it further.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

HYPNOTISM: ITS HISTORY AND PRESENT DEVELOPMENT. By Fredrik Björnström, M. D., Head Physician of the Stockholm Hospital, etc. Authorized translation from the second Swedish edition by Baron Nils Posse, M. G., Director of the Boston School of Gymnastics. 8vo, pp. iv, 126. New York: The Humboldt Publishing Co. Price, 30 cents.

This interesting book contains a scholarly account of the history, development and scientific aspect of hypnotism, covering the manifestations of this condition in ancient and modern times. It describes the popular and unworthy exhibitions of this curious phenomena which formerly prejudiced the scientific world against its careful investigation, and which in the present day serve the purpose of charlatans; and, equally, it describes the steps by which its manifestations have come to be better classified—if not much better understood than when they were used by Egyptian priests or Indian fakirs. In doing this the author speaks of the use of hypnotism as a therapeutic agent, and the possibility that it may be used for immoral and illegal purposes. In conclusion he urges that the law should restrict the use of hypnotism, as a method which may be dangerous to the medical profession.

As a whole, the book is of great interest and very instructive. It is worthy of careful perusal by all physicians, and contains nothing unfit to be read by the laity.

THERAPEUTICS FOUNDED UPON ORGANOPATHY AND ANTIPRAXY. By William Sharp, M. D., F. R. S., etc. 8vo, pp. 203. London: George Bell & Sons, 1886.

One accustomed to the work of reviewing who takes up a book of this kind is tempted to condemn it at once, on its title alone. We doubt if many critics could be found whose experience did not make them regard with suspicion any volume bearing such singular words on the title-page. Still, if the critic be one who regards with favor every attempt to do good in writing books, he does not allow his objections to strange theories and curious modes of reasoning to blind him to motives which are worthy of praise. So, in going through the book, we have not failed to discover the author's manifest wish to be of service to his fellow-men, and his conviction that what seems to him a great truth ought to be communicated to them. This fact makes us lenient toward one who deliberately asserts that almost all medical literature is loaded down with error, and gravely suggests that his views may "do for Medicine what Sir Isaac Newton's law of gravitation has done for Astronomy." But this is the most that we can say; for his book as a whole strikes us as the extravagant production of a mind too conscious of its own operations and too indifferent to those of other men equally sincere and of greater scientific reputation. Those who have time to read such a book will find in this one much that is interesting and much that is suggestive, but this is mixed with much that is repellant from its lack of modesty and much that will appear to most readers as absolutely foolish. The author may have meant well in writing all this, but he is not likely to gain such fame as Newton did—nor is any one who could use the language of Lord Bacon in regard to the stagnation of medical science as if it were applicable in the present day.

A SYSTEM OF OBSTETRICS BY AMERICAN AUTHORS. Edited by Barton Cooke Hirst, M. D., Assoc. Prof. of Obstetrics in the Univ. Penna., etc. Vol. II. Illustrated with 221 engravings on wood. 8vo, pp. xi, 854. Philadelphia: Lea Bros. & Co., 1889. For sale by subscription only.

This volume completes the most important recent addition to the literature of gynecology and obstetrics. The profession in America may well feel proud of what has been accomplished by the contributors and editors.

The present volume of the system of Obstetrics treats of those subjects which are of the greatest interest to the practitioner—the accidents and diseases incident to parturition and the puerperal state; and

their treatment, prophylactic, surgical and medical. Our space forbids a review at length, but we are glad to be able to say that the work is of the highest order. The most striking feature of the book is the space devoted to inculcating the value of antiseptic midwifery. This teaching is set forth admirably, and should be carefully considered by all who are engaged in this important field of medical practice.

CORRESPONDENCE.

Night Terrors of Children.

To the Editor.

Sir: In addition to your judicious editorial comments on this subject, in the Reporter, Oct. 12, 1889, allow me to suggest a factor in the etiology that seems to have eluded observation. From some experience in my own family, I am led to suspect that quite often the malady may be due to a closely fitting night-dress. I observed in the case of my own child, that whenever the night-dress was buttoned tightly about the throat, she was sure to have an attack of night terrors; and that she never had them when the throat was left free and open. In certain positions of the head, the neatly fitting band would occasion constriction of the throat, whence arose mechanical congestion of the brain, which gave rise to the "terrors."

A night-dress, closely fitting around the throat, is a vicious thing, and gives rise to cerebral congestions which may suddenly explode in a convulsion, but much oftener, I apprehend, take the form of night terrors.

Yours truly,

J. P. Hassler, M. D.

Meadville, Pa.,
Oct. 16, 1889.

Union of Cut-off Fingers.

To the Editor.

Sir: I notice in the Reporter, Oct. 5, mention of the reunion of a cut-off finger. During my term in the Dispensary of St. Mary's Hospital, last summer, a man about fifty years old walked in with several of his fingers badly injured, one requiring amputation at the proximal inter-phalangeal articulation. The forefinger just below the distal articulation was cut through with the exception of about an eighth of an inch of skin and fascia, and was hanging loose. I was thinking seriously of completing the amputation, when the patient suggested that he had a finger nearly cut off some years before, and it had been sewed on and grown fast; so, as the cut was a very clean one, I washed the wound well with bichloride solution, and joined the parts with silk stitches without any drainage. The two surfaces united rapidly, and the man has now a useful finger, the only evidence of the injury being an increased circumference due to callus thrown out, and a slight scar. There is no doubt that great numbers of useful fingers are annually sacrificed owing to a too free use of the knife. A little more conservatism in this branch of minor surgery is badly needed.

Yours truly,

A. Hamilton Deekens, M. D.

St. Mary's Hospital, Philadelphia,
Oct. 8, 1889.

NOTES AND COMMENTS.

Plagiarism.

The *Lancet*, Oct. 5, 1889, makes the following handsome acknowledgment in regard to an imposition practiced upon it by a contributor to its pages:

It is, we believe, happily a rare thing for a contributor to this or any other medical journal to adopt as his own "original" contribution the writings of another author. Such, however, we regret to say, has been the case with respect to a paper contributed to these columns by F. W. Allwright, M. D., L. R. C. S. I., entitled "The History and Use of Anæsthetics in Midwifery" (1889, vol. i, pp. 983, 1239; vol. ii, p. 589), which, as our contemporary the *Medical News* (Philadelphia) points out, is practically a transcript of certain pages of the valuable article upon that subject contributed to "Hirst's American System of Gynecology and Obstetrics," vol. i, by Dr. J. C. Reeve. The first volume of the "System" had been in our possession many months, but had not come up for critical notice, as we felt it would be more convenient to review the work as a whole, after the issue of the second volume, which has lately come to hand. Hence our failure to recognize the near identity of the two articles in question. We have communicated with Dr. Allwright, ... who admits that his paper "obtained its foundation from" Dr. Reeve's article, but who does not seem to be aware

of the gravity of the charge of plagiarism which has been fully substantiated against him. Nor does he even apologize to us for having used our pages as a medium for the publication of his unacknowledged transcript. We therefore feel bound to notice the matter thus publicly, and to express to our readers and also to Dr. Reeve our regret that the paper in question appeared in our columns. It is obvious that every journal must have complete confidence in its contributors, and that it is practically impossible to guard against such a practice as that referred to, which for the credit of our profession is, we are sure, of unusual occurrence.

The Dread of Death.

Sir Lyon Playfair, in a letter to Junius Henri Browne, author of a paper with the above title, says: "Having represented a large constituency (the University of Edinburgh) for seventeen years as a member of Parliament, I naturally came in contact with the most eminent medical men in England. I have put the question to most of them: 'Did you, in your extensive practice, ever know a patient who was afraid to die?' With two exceptions they answered, 'No.' One of these exceptions was Sir Benjamin Brodie, who said he had seen one case. The other was Sir Robert Christian, who had seen one case, that of a girl of bad character who had a sudden accident. I have known three friends who were partially devoured by wild beasts under apparently hopeless circumstances of escape. The first was Livingstone, the great African traveler, who was knocked on his back by a lion, which began to munch his arm. He assured me that he felt no fear or pain, and that his only feeling was one of intense curiosity as to which part of the body the lion would take next. The next was Rustem Pacha, now Turkish ambassador in London. A bear attacked him, and tore off part of his hand, and part of his arm and shoulder. He also assured me that he had neither pain nor fear, but that he felt excessively angry because the bear grunted with so much satisfaction in munching him. The third case is that of Sir Edward Bradford, an Indian officer now occupying a high position in the Indian office. He was seized in a solitary place by a tiger, which held him firmly behind the shoulders with one paw, and then deliberately devoured the whole of his arm, beginning at the end and ending at the shoulder. He was positive that he had no sensation of fear, and thinks that he felt a little pain when the fangs went through his hand, but is certain that he felt none during the munching of his arm."—*Science*, Oct. 18, 1889.

Treatment of Pruritus Vulva.

Dr. Percy Newell recommends the following lotion for pruritus vulvæ:

℞ Acid. Carbolici . . . . . gr. xvi
Tr. Opii . . . . . f℥ss
Acid. Hydrocyan. dilut. . . . . f℥ii
Glycerini . . . . . f℥ss
Aquæ destil. q. s. ad. . . . . f℥iv
M. Ft. lotio.

Dr. Scanlan recommends the following:

℞ Cocain . . . . . gr. i
Lanolin . . . . . ℥i
M. Ft. unguentum.

Prevention of Attacks of Migraine.

Dr. Hammerschlag, according to the *Allgemeine med. Central-Zeitung*, No. 39, employs the following combination of remedies for the prevention of attacks of migraine, and states that hitherto it has not failed him:

℞ Caffeinæ citrat. . . . . gr. xv
Phenacetin . . . . . gr. xxx
Sacch. albi . . . . . gr. xv
M. Fiat. pulv. Dis. in capsulas No. X.
Sig. One capsule to be taken, in the intervals of the attacks, every two or three hours.

Phenacetin, he says, does not act so promptly when given alone. This treatment may be kept up until a decided remission occurs, and this does not have to be waited for long.—*Wiener med. Presse*, June 2, 1889.

Etiology and Treatment of Acne.

Barthélemy says, in the *Bulletin Médical*, September 1, 1889, that in acne there exists habitually some dyspepsia, some dilatation of the stomach and divers symptoms connected with it; and that it is only in treating the digestive troubles that one can finally make himself master of the cutaneous affection and have some chance of preventing the provoking relapses. Dyspepsia, however, acts only by preparing the soil

upon which the germ of acne will be sowed and will develop. The germ finds a truly favorable medium only in seborrhœa. This affection is the direct consequence of defective elaboration of food in the stomach, of abnormal fermentations which it undergoes, and of elimination by the glands of the skin of all these products, otherwise toxic—leucomaines, volatile fatty acids, etc., which have been absorbed with the useful products of digestion. According to Barthélemy, there is no acne without preceding seborrhœa. The acne eruption is the result of a sowing of the seborrhœic skin with germs which come from the exterior. These adhere to the skin more readily on account of its oily condition. Barthélemy declares that the eruption is contagious and autoinoculable from contiguous points. That is to say, it is transmissible from one individual to another, on condition of its meeting with a seborrhœic soil; but it is transmitted especially on the same individual from one sebaceous gland primarily infected to other sebaceous glands. Acne is, therefore, to be reckoned among the parasitic affections, along with ecthyma, furuncle, impetigo, etc. The eruption will be discrete or confluent according to the condition of the organism affected, whether depressed or not, and also according to the existence of a more or less seborrhœic condition of the skin. The germs seem, at times, to occupy the skin and remain in a latent condition, to develop anew when a favorable occasion arises.

Treatment—apart from surgical means, which are indicated exceptionally—should consist in cutaneous antisepsis, to combat the germs; and also in gastro-intestinal antisepsis, to render the organism refractory to new attacks by sterilizing the culture medium.

Unfortunate Result of Whitehead's Operation for Hemorrhoids.

Dr. Charles B. Kelsey, reports in the *N. Y. Medical Journal*, Oct. 5, 1869, the history of a patient brought to him a few days before by Dr. Peckham: A woman, aged thirty-five, had been operated upon eight months before in one of the N. Y. city hospitals for hemorrhoids by Whitehead's method. On examination, the anus presented a circle of excoriated mucous membrane ending abruptly in healthy skin. The mucous membrane, which had been drawn outside of the rectum and united to healthy skin, was an inch broad for one-half the circumference of the anus and half an inch broad for the remainder. In other words, the circular incision in the operation was entirely outside the margin of the anus, and the mucous membrane has been drawn down to it, changing a muco-cutaneous opening into one covered by mucous membrane.

The plan of treatment advised by Dr. Kelsey was to dissect this mucous membrane loose, cut it off, bring the skin up as near the verge of the anus as possible, and allow the wound to heal by granulation. A stricture of the anus would, of course, be the natural consequence, but one which Dr. Kelsey thinks should be managed and would be better than the extensive ulceration which is sure to follow the excoriation now begun.

It is needless to say that the patient's present condition is a very miserable one.

Alcohol Treatment of Puerperal Fever.

Dr. A. Martin delivered a lecture, on June 28, before the Berlin Society of Obstetrics and Gynecology, in which he mentioned anew the favorable influence of alcohol upon the course of puerperal fever. The administration of alcohol in puerperal sepsis was first recommended by Breisky, and eleven years later was again taken up by Runge and thoroughly discussed in several communications. Dr. Martin, whose cases were for the most part in private practice, complains that most of the cases of puerperal sepsis in private practice are brought to the physician's knowledge for the first time when the infection has already become general, and when the prospects of a local treatment are least favorable. He communicates an account of 18 of the cases in which the administration of alcohol had been possible. Five of these 18 died. The cases were of extraordinary severity, in which treatment with alcohol was begun for the first time when the fever had raged for a week and the patients had been weakened by severe complications. Thus, there existed in several cases, which finally ended in recovery, purulent parametritis, ichorous decomposition of the ovum, pyemia in one case with panophthalmitis and purulent destruction of a hip-joint; three of the cases were reckoned as of pyemia and 15 as of septicemia. Four of the 18 patients were taken sick in connection with an abortion,

which was criminal in three cases; the other fourteen patients had given birth at the normal end of pregnancy, in three cases by artificial aid. In 4 cases local treatment was employed in addition to the use of alcohol, while in the other cases no advantage was to be expected from local treatment, except as disinfecting washes.

The alcohol was given in the form of cognac, rum, Burgundy, Bordeaux, and southern wines, for the most part mixed with champagne; the most concentrated food possible was also given. It frequently required, however, energetic persuasion on the part of the physician and of the attendants to induce the patients to take the drinks, which often had to be changed. Diarrhœa occurred at times in nearly all the patients, and when it did the drink was changed, champagne being stopped and mucilaginous drinks being given. In one of the cases, which is given in detail, the patient took within a period of six weeks the following: 17 bottles of cognac, 13 of Bergundy, 37 one-half bottles of champagne, 4½ bottles of other heavy wine, and 6 bottles of porter. Martin does not think, as Breisky did, that the favorable action of alcohol consists in its influence in reducing fever, but rather in a strengthening of the heart's action and in the increase of the resisting power of the individual against the ravaging action of the infection.—*Deutsche med. Wochenschrift*, July 25, 1889.

Treatment of Incontinence of Urine with Antipyrin.

The *Gazette Hebdomadaire*, September 27, 1889, contains an abstract of an article by MM. Perret and Devic, on the treatment of incontinence of urine with antipyrin, which was published in *La Province Medicale*, June 8 and 29, 1889. The treatment in question was tried upon some children whose nocturnal incontinence had resisted the bromides, belladonna, and hydrotherapy. During a period of seven days, at six and eight o'clock in the evening daily, two doses of seventy-five centigrammes each (nearly twelve grains) were given. The result was a diminution in the incontinence. The treatment was then suspended for eight days, but the amelioration continued. The following week the antipyrin was administered in the same doses as at first, and cure appeared to be final.

It is recommended that the remedy should be prescribed at intervals, and continued for a long time.

An Epidemic of Herpes Zoster. The Etiology of the Affection.

Kaposi, in the *Wiener med. Wochenschrift*, Nos. 25 and 26, says it is generally admitted that herpes zoster is a trophic disease of the skin. It can be produced by a lesion of the invertebral ganglia. It is met with following tumors, caries of the vertebræ, and fractures, etc., which compress or destroy the ganglia. Hysterical patients are frequently subject to it. There are some cases, however, in which it is difficult to discover the cause of the lesion of the ganglia which provokes the herpes zoster, and as, on the other hand, there occur true epidemics of the affection, it may be asked if the disease is not of infectious origin. A number of reasons may be adduced in favor of the latter hypothesis. First and foremost, there are the epidemics. Kaposi in particular, in the interval between November, 1888, and February, 1889, saw more than forty cases of herpes zoster, although ordinarily the affection is very rare. Again, the epidemics occur at certain seasons of the year, particularly in the spring and autumn. Kaposi also invokes in favor of his hypothesis the observation that generally a person has herpes zoster only once. The rule is not absolute, however, since he attended one patient in his eleventh attack. Finally, it is remarkable that each epidemic has its special type. In some periods the affection is grave, in others benign. In the epidemic Kaposi observed, all the cases were remarkably benign. Only the infectious diseases, such as scarlatina, measles, typhoid fever, and variola present such temporary variations in their intensity.

If herpes zoster is infectious, how is its pathogeny to be interpreted? Kaposi thinks that there is a general infection exerting its action upon the ganglia and determining secondarily a cutaneous eruption. He admits this hypothesis because other general diseases, in particular certain intoxications, can also determine herpes zoster. Carbonic oxide, and arsenic, for example, frequently provoke this eruption. As in the case of poisoning the herpes can be explained only by a previous alteration of the nervous centres, so the same interpretation must be adopted to explain the infection of herpes zoster.—*Bulletin Médical*, September 18, 1889.

NEWS.

—Dr. R. H. Hamill has removed to 2018 Pine street, Philadelphia.

—The American Public Health Association held its seventeenth annual meeting in Brooklyn October 22–25.

—Johnstown, Pa., was free from typhoid fever Oct. 16, and, on the authority of the Red Cross Association, may be considered fairly safe from danger for the present season.

—According to the latest advices, cholera continues to be epidemic in the Philippine Islands, although the disease is now on the decrease. The number of cases reported so far have been 22,397.

—Diphtheria is said to be prevailing to some extent in Allentown, Pa., and the ravages of the disease have been severe in some families. One man lost three children within a week and had two other children very sick.

—There has been an alarm at Yale College, in regard to typhoid fever. Exaggerated accounts led to the fear that there was danger of a epidemic; but from the latest and most reliable accounts this seems to be unlikely.

—At the semi-annual meeting of the Philadelphia Pathological Society, Oct. 24, Dr. John Guiteras delivered an address upon Some Features of Southern Pathology. After the meeting a reception was given to Dr. Guiteras at the University Club.

—The Charité Hospital in Berlin, which is so well known as the cradle of many important medical investigations and the school in which many lights of the profession have been trained, is about to be extensively enlarged and to have a new Polyclinic added.

—An epidemic of small-pox has broken out on the Austrian frontier. In Jägerndorf 329 cases have been reported and 37 deaths, and in Gotschorf, a small town with about one thousand inhabitants, 55 cases with 4 deaths. The epidemic shows no signs of abating.

—Another sporadic case of yellow fever has been reported at Key West, Florida, and in consequence quarantine restrictions have been resumed. The patient is a man, who left Havana on September 21 for New York by sea, came from New York by rail to Key West, October 2, and was taken sick October 22, in a locality of the city distant from that of the former cases.

—Among the ten true bills of indictment found by the Camden Grand Jury, Oct. 21, was one against Dr. S. Preston Jones for maintaining a nuisance in the shape of a private insane asylum at Merchantville, N. J. Dr. Jones was formerly in charge of the Male Department of the Pennsylvania Hospital for the Insane, and his fellow-townsmen at Merchantville found themselves annoyed by the patients in his private asylum.

OBITUARY.

PHILIPPE RICORD.

Dr. Philippe Ricord, the celebrated teacher of venereal disease and syphilography, died in Paris, Oct. 22, 1889, at the age of eighty-nine years.

Though Dr. Ricord was accounted a French physician and was a member of the Academy of Medicine, he was born in Baltimore. He was the grandson of a distinguished physician of Marseilles and a brother of J. B. Ricord, the author of works on language, medicine, and natural history, many of which were first published in this country. Under this brother he made a number of scientific studies, and began the study of medicine in Philadelphia. In 1820 he went to Paris. He was admitted to the study of surgery—first at the Hôtel Dieu under Dupuytren, then at the Pitié under Lisfranc, receiving the degree of Doctor of Medicine in 1826. In 1828 he delivered a course of lectures on surgery in Paris and in 1831 he was appointed Surgeon-in-Chief to the Venereal Hospital of the Midi. At this hospital, from which he retired on account of age in 1860, he gained a great reputation as a syphilographer. By a decree bearing date July 28, 1862, he was appointed physician in ordinary to Prince Napoleon, and on October 26, 1869, was named consulting surgeon to Napoleon III. He became a Commander of the Legion of Honor, and in 1871 was made a Grand Officer for services during the siege of Paris. He also received many foreign decorations. He has been an active writer, several of his works on surgery having been crowned by the Academy of Sciences. For many years he was known in Paris as "the great American doctor," and he has always had a warm interest in his native land. Ricord leaves a name never to be forgotten in the history of syphilography, and, during the active years of his life, he was the most famous specialist in his line in the world.

EVERY PHYSICIAN prescribing COD LIVER OIL (and who does not?) wants to know that his patients get the best that can be obtained. This is effectually secured by specifying "**BAKER'S**" whose firm (established in 1830) have given the greatest attention to the improvement and perfection of this all important remedy. In the various conditions in which Oleum Morrhuæ is indicated the Practitioner must decide the best form of administration. To meet such conditions we offer:

BAKER'S COD LIVER OIL.

BAKER'S EMULSION WITH HYPOPHOSPHITES OF LIME AND SODA.

Baker's C. L. Oil with Ext. of Malt.

Baker's C. L. Oil, Lime and Wild Cherry.

Above goods are accessible through the wholesale trade to all Retailers, and may be prescribed with the utmost confidence as to Purity and Excellence.

JOHN C. BAKER & CO., PHILADELPHIA, PA.

A Peerless Chemico-Physiological Food and Restorative

Crystalline Phosphate

A TISSUE FOOD

PHOSPHATIC FOOD PRODUCTS TRADE MARK

Contains all essential inorganic components of the tissues in a semi-solid, easily soluble, crystalline mass,

COMPOSED OF

ACID PHOSPHATE OF CALCIUM.

WITH

Acid Phosphate of Magnesium,
" " " Iron,
" " " Sodium,
" " " Potassium,
Chloride of Potassium,
" " Sodium
Sulphate of Potassium,
and Phosphoric acid.

INDICATIONS:

STOMACH DISORDERS, such as Indigestion, Flatulence Gastric Catarrh, and Poor Appetite, Constipation, etc.

WRONGS OF NUTRITION, as in Scrofula, Rickets, Caries, Marasmus, Delayed Union of Fractures, Necrosis of Tissue, Difficult or Delayed Dentition and Development, etc.

NERVOUS AND GENERAL DEBILITY AND SLEEPLESSNESS, as from Sexual Excess, Venerial Disease, Childbearing, Nursing, Loss of Blood or other fluids, Menstrual and other Diseases of Women, abuse of Alcohol, Tobacco and Narcotics, Protracted Illness, etc.

PROF. KONN B. SAYRES, M. D., Demonstrator of Anatomy, Miami Medical College, Cincinnati, O.

I am pleased to inform you that I have during about six months last past made a critical trial of your **Crystalline Phosphate,** in various cases of mal-nutrition, nervous prostration, atonic dyspepsia, insomnia and kindred derangements of the vital functions, which has demonstrated the fact that it is a preparation of *very great value.* I believe your representations concerning it are fully justified by actual and palpable results in my practice, and I very cheerfully recommend it, knowing that a fair trial will prove it worthy of the confidence of the profession.

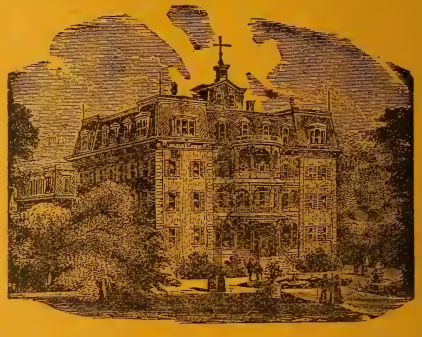
BURN-BRAE.



This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe, and healthful HOME.

Resident Medical Officers:

CLINICAL LECTURE.

DOUBLE OVARIOTOMY — GYNECOLOGICAL DIAGNOSIS.

BY WILLIAM GOODELL, M. D.,

PROFESSOR OF GYNECOLOGY IN THE UNIVERSITY OF PENNSYLVANIA.

Gentlemen: Before beginning my lecture I beg of you that, during the coming session, no one leaves the room while the peritoneal cavity of a patient is open, and that no applause or noisy demonstration of any kind be indulged in, until the wound is closed. My reasons for this request are the following: In the former case, septic germs are liable to be introduced from without through the opened door; and, in the latter, dormant, impure dust is floated up from the floor to fall down upon the wound. Trusting that you will scrupulously grant this request, I shall now bring in a case for laparotomy.

Double Ovariotomy.

This patient, with a large abdominal tumor, is fifty-three years old, married and the mother of ten children. Three years ago she ceased to menstruate; but a few months since her catamenia returned not only with greater severity but also with increasing frequency. This symptom generally points to the presence of a uterine fibroid tumor; but, upon using the sound, which passes in only three and a half inches, the womb is found to be movable, though with difficulty, and separate from the tumor. As the latter demands some effort to raise it up, I fear that there are adhesions on its lower surface. Preparatory to the operation, the patient's bowels were moved yesterday by castor oil, and an enema was given this morning. She has had no solid food for twenty-four hours, and since this morning her abdomen has been kept covered with a napkin, soaked in a weak (1 : 4000) solution of the bi-chloride of mercury.

Boiling water is now poured over the instruments; for heat is a better germicide than carbolic acid, which however I add later—more to cool the water, than to make the canonical two per cent. solution. Having then washed my hands in a 1 : 1000 solution of the bi-chloride, and my assistant having done the same, I cut down through the skin, superficial and deep fasciæ in the median line, just below the umbilicus, by an incision five inches long. The præperitoneal fat is now divided carefully until the peritoneum is exposed. Before this is divided, all bleeding vessels are secured with clamps, and the womb is thoroughly cleansed with a sublimated solution. I now catch the peritoneum by two forceps, raise it up, so as to avoid any intestine, and carefully divide it. This being done, the cyst comes into view. It is of an acreous, or pearly, color and therefore is undoubtedly ovarian.

The trochar is now plunged into the upper part of the tumor, and, as you see, a coffee-like fluid escapes, which exhibits on its surface minute sparkling points, caused by crystals of cholesterine. There fortunately are no adhesions, and the sac when emptied is readily drawn outside through the incision. Sponges are quickly packed into the abdominal cavity, and the pedicle is secured by a ligature tied as close to the womb as possible. The empty sac is next cut off and removed.

I now strip off a redundant portion of the pedicle and take a look, as is my custom, at the other ovary. Upon it is a small cyst. I shall, therefore, likewise, take it out, although its removal will arrest menstruation, and bring on the change-of-life. Yet in this case this cessation will be beneficial on account of the uterine hemorrhages. In all oöphorectomies the ovarian tissue must be wholly removed. Otherwise some germinating stroma may remain behind to keep up menstruation. Hence, in this case, I am obliged to tie very close to the womb. The sponges are now removed, washed and replaced. There were no adhesions present, but the extreme shortness of the pedicle made it appear as if there were.

Now I proceed to close the cavity. These needles, threaded with silk, have been immersed in a saturated solution of carbolic acid for seven hours. I pass them from within out, including all the tissues, especially the peritoneum; because, on account of its greater vascularity, it unites more quickly than the other tissues, thus securing the cavity of the abdomen from pus or any other septic material which may develop in the wound above it. The elasticity of the skin makes the incision much smaller now, since the tumor has been removed. In closing it each one of the tissues must be included within the sutures, in order to obtain perfect coaptation and to prevent a hernia; which may, however, occur, in spite of every precaution, both in short and in long incisions. The sponges being now removed from the abdomen, they and the instruments are carefully counted. This taking count of stock is very necessary, for a number of women have lost their lives because a sponge or an instrument has been left behind, even by careful operators. As during the operation the smaller cyst burst and its contents escaped into the abdomen, I shall with a syringe from which the air has been excluded, thoroughly irrigate the abdominal cavity by passing the nozzle of the syringe into Douglas's Pouch and by pumping water in, until it comes out wholly clear. A drainage-tube is put in temporarily, in order to get rid of any water that may have been left. When all the stitches are tied I shall compress the abdominal wall, force out all the water and take the tube out. The dressing that I use is as follows: 1. Iodoform sprinkled over the wound, especially about the navel, which is a favorite harbor for germs; 2. Iodoform gauze; 3. Bichloride cotton; 4. Baked cotton, which is held in position by adhesive strips and further secured by a broad binder that has been previously passed round the body.

The after treatment will be simple. The patient is to have no food for twenty-four hours. Then she will have a half ounce of milk or of broth every two hours, later one ounce, then still more, especially after wind begins to escape from the lower bowel. The stitches will be removed in a week and, if everything goes well—as it most likely will—her temperature will not rise above 100° F. No opium will be given, if it can be avoided; because, in the first place, it lessens peristalsis and thereby interferes with the escape of wind and the movement of the bowels; and, in the second place, by paralyzing the bowels it encourages adhesions. Besides, the pain is not generally severe enough to call for the use of opium.

Gynecological Diagnosis.

The next patient, whom I bring before you merely in order to make a diagnosis, is

twenty-seven years old, married and the mother of three children, the eldest of whom is nine years old and the youngest two. She was healthy as a girl, menstruated at fifteen and was married at seventeen. Three months ago she began to have pain in her back and right flank. Three weeks ago she was tapped of some colloid fluid, without emptying the tumor, and in the short interim the abdomen has been rapidly increasing in size.

The first question I ask is: Is the fluid free or encysted? If free, we ought on percussion to have resonance in the median line from the floating up of the intestines and to have dulness in the flanks. But an examination reveals marked dulness in the right flank, which increases as we get nearer the median line. The lower part of the abdomen is also dull, while fluctuation is obscure.

The right side of the abdomen is occupied by a hard body, which the patient says was more apparent directly after the tapping. The tumor is not continuous with the liver, because the resonant colon intervenes, and, moreover, she says it began below and grew upward. Certainly we are dealing with an abdominal tumor containing some fluid, and there appears to be ascitic fluid as well.

The woman's monthly periods have not appeared since July, and her breasts are very much withered since then. Upon examination I find that the cervix is drawn up behind the pubis and that the womb gives a measurement of more than four inches. The womb is firmly fixed, but it appears to be merely attached to the tumor and not a part of it. The white and, therefore, old lineæ albicantes on the abdomen make us certain that there has exisied at some previous time a distension of the abdomen. Now, if a woman shows these old scars on the abdominal wall, and bears no evidence of chronic disease, we can be morally, although not absolutely, certain that she has once been pregnant. For, if they had come from a dropsy due to hepatic, cardiac or renal disease, the organic lesions would most likely remain constant. Again, were these cicatrices due to distension from the tumor now in the abdominal cavity, they would be purple, not white and glistening.

The rapidity of growth in this tumor, these blue tortuous veins on the abdominal wall from deep seated obstruction, make me incline to the diagnosis of malignant disease of an ovary. I shall, however, in a few days make an exploratory incision to see what can be done. If the tumor be a sarcoma, it may be successfully removed and the patient may live for many years before it returns. If it be a carcinomatous growth, adherent in many places, the exploratory incision can be closed up and her life will not be shortened thereby. Finally, if the growth prove malignant and yet have a pedicle, it can still be removed and life may be greatly prolonged, for as the woman now is I do not think she will live three months longer.

COMMUNICATIONS.

THE TYPHOID STATE.

BY J. CHRIS LANGE, M. D.,

PROFESSOR OF THE PRINCIPLES AND PRACTICE OF MEDICINE AT THE WESTERN PENNSYLVANIA MEDICAL COLLEGE, PHYSICIAN TO THE WESTERN PENNSYLVANIA HOSPITAL, PITTSBURG.

The typhoid state or the typhoid condition presents its phenomena in various diseases. These phenomena are referable to the nervous and muscular systems. In the northern temperate zone they are observed in greatest perfection of development, as well as with greatest frequency, in typhoid fever, and from no better grounds have grown: first, the application of the term "typhoid" to this state, and, next, the questionable custom of qualifying the name of other diseases, when complicated by this state, with the prefix or suffix "typhoid." The term "typhoid," used to designate that particular typhus-like fever is an example of unscientific nomenclature, and it is as desirable as it is difficult to find a better for this purpose. No adequate excuse can be offered, however, when this term is used to qualify or describe other diseases, and the abolition of the custom would be a desirable step in nomenclature. The undesirability of using a term whose primary significance implies a fever of specific origin, with a specific lesion, to designate other diseases is seen in the obscurity in which it involves a pneumonia complicating a typhoid fever and a "typhoid pneumonia."

The "typhoid *state*" is common to many diseases; it is not presented in every case of typhoid fever; and it is more frequent in typhus and some other diseases than in typhoid fever. Therefore, were it not that custom makes the law, it would be as proper

in every aspect to describe a "typhoid" typhus fever or a "typhoid" typhoid fever as it unfortunately is to describe a typhoid pneumonia or a cholera typhoid.

From these considerations it follows that the term "typhoid" embraces two very different meanings. First, it designates a specific fever, and next a certain condition of the nervous and muscular systems. Further, this condition of the muscular and nervous systems is manifested in various diseases—in typhoid fever as well as in others; but it is in no manner more closely related to typhoid fever than to other infectious diseases; it is no more essential to the clinical history of typhoid fever than to that of other infectious diseases; and it is as much entitled to rank as a complication of typhoid fever as of any other disease. It is a condition not peculiar to typhoid fever but quite distinct from this and bears the same name only because other diseases do not so frequently present themselves possessed of duration and gravity sufficient to produce this state, as typhoid fever does. The typhoid state is produced by the duration of disease or by its intensity. It is an ataxy—a disturbance, a confusion. Its phenomena are muttering delirium, hallucinations, coma-vigil, typho-mania, deafness, muscæ volitantes, picking at the bed-clothes or body-linen (carphologia), inco-ordinate voluntary movements, difficulty in swallowing, changed or inaudible voice, the dropped jaw, the tremulous tongue, sinking down or sliding down in bed, vomiting, diarrhœa, tympanites and relaxation of the sphincters. The presence of few or many of these signs, symptoms and phenomena declare the presence of the typhoid state in disease, and they are presented in conjunction with those characteristics of the disease it complicates.

The pathogenis of some of these symptoms is obscure; that of others is well understood. The state itself is observed to precede death by starvation. It is commonly presented in acute diseases involving marked innutrition, exhaustion of all muscular tissue and especially of the heart. So certainly and frequently do prominent phenomena of this state follow rapid and great muscular exhaustion, and particularly heart exhaustion, that this deserves to be considered as one of its causes. When the typhoid state is induced by heart exhaustion (which is not however assigned as its solely acting cause) then it occurs late in disease, and those of its phenomena which are referable to the muscular system are pronounced and prominent.

Again the typhoid state comes in consequence of exhaustion of the nervous system and especially of the brain. Mental inquietude, fright, terror, repeated mental perturbations and shocks, delirium, hallucinations, the decided disturbances of encephalic circulation and nutrition, but particularly the abolition of sleep, are the factors of disease engaged in brain exhaustion. Sleeplessness is beyond doubt the most potent of these, and seems of itself a sufficient as well as a frequent cause of the typhoid condition. When the typhoid state is produced by brain exhaustion, whether this happens early or late in disease, then the phenomena of the condition present a greater likeness to those of alcoholism. There is greater mental excitement; there is less physical debility; the patient may be able to walk; there is less muscular inco-ordination but more tremor, and hallucinations are more frequent and obstinate.

A factor of disease frequently assigned as the third cause productive of the typhoid state is high temperature. Personal observation directed to this point constrains the belief that high temperatures are not entitled to rank as causative of the typhoid state. High temperatures are rare except in the infectious diseases; and it may be arbitrary to certainly ascribe the occurrence of the typhoid state in these diseases to the temperature elevation, if this be high, and to quite ignore the influence of the infection. It is impossible to accept the widespread theory that high temperatures determine the occurrence of the typhoid state. The unbiased consideration of personal experience forbids it. High temperatures exert baleful influences upon the nervous system as well as upon the body at large, yet it is quite common to observe high temperatures continue many days, the patient feeling comparatively comfortable, and presenting no symptom of the typhoid state. Equally as frequent is it to find very moderate temperature elevations in the infectious diseases while the patient presents marked phenomena of this state. In diseases certainly not infectious which present high temperatures: for instance insolation when the patient is not comatose, the typhoid state is not presented. It is not forgotten that in certain cases of heat exhaustion, particularly in the tropics, when the duration of the disease occupies many weeks, the typhoid state precedes death. But this

happens late in the disease; the temperature then is no longer high; the typhoid state is obviously due, not to temperature elevation, but to one or both the previously mentioned causes: heart and brain exhaustion. The same is true of inflammations, certainly not infectious; and that the typhoid state frequently complicates croupous pneumonia and acute tuberculosis constitutes additional evidence that these inflammations are infectious diseases. A high temperature persists without causing the typhoid state on the one hand; and, on the other, the typhoid state is presented in the infectious diseases without the occurrence of high temperature. These considerations constrain the belief that high temperature, although commonly co-existing with the typhoid state, is not the cause of this latter but a concomitant; and that both are consequences of the special poisons of the infectious diseases; and further, that when the typhoid state is presented in diseases certainly not infectious, this is due to either heart or brain exhaustion.

If it be asked why, if this state be due to the presence in the blood of the special poison of an infectious disease, it is not presented in all cases, it can be answered only that the patient who presents this state has received a greater quantity of the special poison, or that the special poison he has received is of greater activity or of greater virulency than the poison received by another patient who does not present the typhoid state; or, finally, that the first possesses a greater susceptibility to the action of this special poison than the last. With our present knowledge, in short, the presence or absence of the typhoid state in an infectious disease must be ascribed, on the one hand, to the properties of the special poison, or on the other, to the susceptibility of the patient. And the same answer is pertinent to the question: Why is not a high temperature always presented?

The phenomena when the typhoid state is due directly to the special poisons of the infectious disease constitute evidence that a most profound impression has been made upon the brain and nervous system. This state so produced comes early, immediately. When these disease germs in the blood of the patient have multiplied sufficiently or have matured sufficiently, or have produced sufficiently their toxic principles—that is, when the period of incubation has terminated—then, if the typhoid state be due directly to the action of these poisons upon the brain and nervous system it may come as rapidly as narcotism can be induced by opium. This is observed oftenest in diphtheria, scarlatina, typhoid fever and cerebro-spinal fever. In the great majority of such cases the typhoid state has a duration of a few hours or a few days and terminates in coma; and coma in this connection is synonymous with death. Such patients are overwhelmed by these special poisons, and are stricken as though felled with an ax. Such attacks by these special poisons exemplify all the horrors and terrors embraced by the word "malign." They are malignant. Those cases in which coma does not follow the typhoid state are exceptions to the rule. When this happens, first its graver and then its other phenomena gradually disappear and finally the patient presents only the symptoms proper of his disease and has to contend only with its usual and characteristic dangers. An interesting question in such cases is: Has the special poison wholly or partly been eliminated? The growing probability that certain toxic alkaloids, which seem invariable products of organized germs in the blood, are causative of the intoxication of such infectious diseases, and, indeed, of the diseases themselves, and the fact that these alkaloids have been extracted from the urine of such patients, make it likely that in a few hours, perhaps immediately, after the manifestation of an infectious disease elimination of these special poisons is already under way, and that the urine is one medium for their extrusion. Despite this probability in explanation of recovery from such malignant attacks, another is deserving of equal consideration. It is, the genesis of a tolerance of these poisons. If the first onslaught can be met and withstood, then a tolerance is established which grows from day to day. A study of other conditions of disease establishes this as a probability in explanation of recovery in such cases. Such a tolerance is established, for instance, in uremia, in opium narcosis, and in carbonic acid poisoning, which, though not identical, are analogous conditions.

The typhoid state, whether induced by heart exhaustion, brain exhaustion, or the infectious poisons, presents no special lesion. It possesses no anatomical character. The lesions appreciable are those characteristic of or peculiar to the disease which it complicates. The great and rapid waste required to produce this state presents, besides adipose

atrophy, that form of fatty degeneration of muscular tissue, particularly of the heart, which is called granular. When this state is due to brain exhaustion or to the direct action of the infectious poisons upon the brain and nervous system, no lesion is discoverable which deserves to be regarded as causative of the symptoms observed during life. The anatomical changes in the brain bear no relation to the phenomena of this state. In all infectious diseases, except cerebro-spinal fever, no anatomical change, gross or microscopical, accounts for the symptoms observed during life. This is true of delirium, mild or violent, of the intensest cephalalgia, of pupil eccentricities, of coma, of convulsions and tetanic rigidity of the cervical and dorsal spine. The same is true of the phenomena of the typhoid state. They cannot be referred to anatomical change. Sometimes punctiform meningeal blood extravasations are discovered; sometimes there is meningeal opacity; sometimes slight meningeal œdema or cerebral œdema; oftenest only the loss of normal brain consistency observed after chronic or very exhausting acute disease. Certain it is, that these abnormalities bear no relation to the severity of the symptoms.

The prognosis in any case of disease is increased in gravity by the presence of the typhoid state. This is true if this latter be due to heart or brain exhaustion; if it be due directly to the infectious poisons then the prognosis is almost necessarily a fatal one. In many cases, however it be caused, it is but the precursor of death. When this is true, the patient grows gradually more stupid, and finally sinks into that complete muscular relaxation accompanied by the abolition of the general and special senses and consciousness, which is called "coma." On the other hand the typhoid state, except when due to the infectious poisons, does not involve the occurrence of coma. Very many cases recover. The prognosis depends to a very considerable extent upon what disease this state complicates. For instance, when it occurs in typhoid fever the prognosis is much better than when it occurs it diphtheria. Further, the prognosis is influenced by the time of its occurrence and by the efficacy of remedies addressed to it. Again, the prognosis is decidedly dependent upon the character and number of its phenomena, that is, upon the intensity of the state. The gravest of these are: growing stupor, vomiting, diarrhœa and tympanites. Next in order of gravity may be placed the extreme muscular exhaustion indicated by falling of the jaw, the inability to move a limb, the inertia manifested by sliding down in bed, the change in the first heart sound, with sighing or shallow respiration. Relaxation of the sphincters, the tremulous tongue, carphologia and subsultus are common in cases of typhoid fever which recover. In cases of pneumonia which recover they are not so common. The same is true, but to a lesser extent, of typho-mania and coma-vigil. These considerations in conjunction with the signs, symptoms and phenomena proper to the disease which this state complicates are of weight in prognosis.

Immediately the typhoid state is declared in any disease, this latter, as far as treatment is concerned, sinks into insignificance. The phenomena of this state sufficiently demonstrate the urgent necessity for its removal, and present imperative indications for treatment. Remedial measures are addressed directly to this state, its cause or its phenomena. Although in a given case one or the other may be more active, heart and brain exhaustion go hand in hand in the production of this state. Acute general disease is in possession of no weapon with which it may destroy the heart and leave the brain uninjured, or paralyze the brain and leave the heart intact. But, from the course of the disease, its incidents, events, its ravages and spoliations, the indications come which designate which of these two co-operative causes has been most potent to produce this state. If this be heart exhaustion, then stimulation by the alcoholics undoubtedly deserves first rank. How rarely when such a patient recovers does his physician doubt that the alcohol has contributed to this desirable end! The good effects of dietetic, hygienic and medicinal measures are insufficient, and the dire ravages of the disease have not yet ceased; disease has almost lived its time, but not yet quite. What, but this "indirect food," alcohol, with its compelling power to make both ventricles renew their strength, can make the sluggish stream of blood move on, clearing the brain, brightening the eye, steadying the muscles, holding in tight embrace vitality which otherwise assuredly would have left its tenement? Such cases are rare, but they occur and are exemplifications of the power and beneficence of our art.

When the abolition of sleep is the pronounced cause of the typhoid state, then

the object of treatment is to procure sleep for the patient. In such cases this state gives warning of its approach. It never comes as an unheralded calamity. Its approach has precursors. Its advent is preceded by its lighter symptoms. Because of this, when it has come, remedial succeedaneums again have proved their right to grow a hopeful faith and then to blast it. They have been tried—tried and found wanting. So when the typhoid state has come in all perfection there is but opium. Opium and alcohol! It is a pregnant commentary upon a therepeusis, growing more boastful year by year. The limits of this paper forbid a defence of opium in this condition. As it is true that in certain cases the typhoid state will terminate without its use and the patient recover, as it is true that in other cases, particularly in pneumonia, its administration will but favor the growing tendency to coma, *i. e.*, to death, so it is also true that in certain other cases its exhibition will save life.

Little is to be said of the treatment when the typhoid state results from the direct action of the infectious poisons upon the brain and nervous system. A proper measure is to facilitate all excretion. Another is to endeavor to assist the brain to resist the first attack of the poison. If this can be accomplished, a little later, in a few hours or days, a tolerance has been established and elimination to some extent has happened. The employment of such measures is a forlorn hope; exceptionably success rewards it.

In concluding I will give a brief account of the progress, treatment and issue of a case which illustrates much of what I have said above.

In a house containing two younger children with diphtheria a girl aged twelve and previously well was seized by a pronounced chill with rigors at midnight. In the morning she was blanched and cold; the thermometer registering 103° in the rectum, her pulse being 120, weak and narrow. Her eyes were closed and she was stupid. She was relaxed; her arms lay extended on either side and twitched; her limbs remained motionless, but for their twitching, wherever they were placed. Her face twitched like that of chorea, her nose looked sharp and pinched and about the alæ, on her lip and cheeks, the skin was white and bloodless. She breathed irregularly and shallowly. She protruded her tongue slowly and it trembled. The conjunctival vessels were prominent and the secretion between the lids plentiful and gluey. The pupils were of normal size but sluggish. She presented a light film upon both tonsils and her cervical glands were enlarged. Twenty-four hours later she was not so white and cold. Her temperature was 103°, her pulse 120 and fuller. She was vomiting, had had hiccough and four involuntary watery discharges. She had been twice catherized and presented an active and noisy peristalsis with tympanites. She was more stupid; she no longer protruded her tongue. Her lips were dry, brown and cracked. She heard nothing; she evidently saw nothing; her eyes were wide open, glassy, and fixed intently upon some far distant place; they looked past every one and everything the room contained. Her lips trembled and her hands quaked. Slowly but wildly, with inco-ordinate jerks, her hands reached for objects in the air, then fell and tremblingly searched on the bed-clothes for what they could not find. But her eyes never followed nor noted her hands; they were engaged too intently in staring at far-away places, at objects they could not reach. She constantly murmured undistinguishable words and frequently cried loudly for her mother. Her mother was constantly with her and constantly assured her of her presence, but she could not appreciate it. Her hands would convulsively clutch her mother or anything they happened to touch, immediately throw off the object and then resume their vain and endless search for objects in the air and on the bed-clothes. On the third day her eyes were closed, and her hands rested from their fruitless search. They were still; that is to say they lay in one place, but the subsultus still twitched them. She could again protrude her tongue; she could be made to hear, and she could be made to appreciate her mother's presence. On the fourth day intelligence was in her eyes—the typhoid state had terminated. Her treatment consisted of one-eighth grain and following this one-sixteenth grain of morphia given every third hour, and maintaining the hyperactivity of the skin by means of hot bottles and wet towels under her blankets. She now presented a collar of brawn from ear to ear and a leathery membrane on both tonsils. Treatment for diphtheria was now begun and in two weeks she was a convalescent.

INOSITE IN THE URINE.[1]

BY WILLIAM S. DISBROW, M. D.,

NEWARK, N. J.

The importance of the chemical examination of the urinary secretion in cases of suspected diabetes is recognized by all to be worthy of the closest attention, and any improvement or discovery made in this line of inquiry, becomes of more or less value in the recognition of glucose. In the examinations made in reference to direct treatment, and in insurance cases, where the early diagnosis of incipient mellituria is desirable, it is necessary to know definitely whether a specimen of urine contains this sugar or not, and it is my desire to show where I made a mistake, and what I believe was the source of my trouble, and to explain a doubtful reaction. I wish it understood that the large number of compounds usually acknowledged to react in the presence of Fehling's solution, have all been noted, except the greenish coloration, which Dr. Squibb claims is due to sugar, and that this reaction is due to another of the same group of carbo-hydrates.

Of course it is expected that any one can test for sugar; and any one who fails to recognize a diabetic from a non-diabetic urine would be considered very shallow.

All this I admit; but when glucose is in minute quantity, and the reaction is questionable, the answering of the question is not always an easy one.

I consider that standard Fehling Solution made by Dr. Squibb is the most reliable test we have; but I take exception to the statement that the greenish coloration which is frequently found in the use of this reagent, is due to one per cent. of glucose, and I believe the remark has led to great injustice to the parties interested. This I think can be proven by the testimony of others who have investigated the subject, and, in a letter which I received from Dr. Squibb some time ago, bearing on this subject, he stated that this reaction may be due to some other constituent, and recommended the fermentation of Doremus.

In specimens of urine which were known to be free from glucose I have often seen this reaction; the olive green coloration which upon subsidence leaves the supernatant liquid the original blue with no reduction of the copper salt. This reaction was stated to have been indicative of glucose in the following incident, which was the starting point in my backsliding from the infallibility of this test.

About one year ago I received from one of the largest insurance companies of this city, a specimen of urine with the request to carefully examine,—particularly for sugar. This was done with a negative result, but to my chagrin I was informed by the medical director, who is a man of superior attainments and of large experience, that he had examined it previous to sending it to me, and found that it contained sugar. Feeling certain that I was still right, I requested that it be sent to New York to be analyzed by some one whose report would be authoritative. It was sent to the Carnegie Laboratory, whose report was negative—it contained no glucose. The Doctor then asked me what it was that gave the reaction? I remarked, that I did not know; but I have, to my satisfaction, since found out.

Looking up the subject, I find that this claimed the attention of Rolfe; but it was Oliver who first stated that it might be muscle sugar or inosite.

Tyson questioned the reliability of the reaction, as not being sufficiently distinctive, and by the introduction of his method, which isolates in the crystalline form the compound, he proved that the supposition of Oliver was correct.

A few remarks on the chemistry of inosite will not be out of place; so I shall in a few lines describe its most important features.

Inosite, Phaseomannite, or Muscle Sugar, $C_6H_{12}O_6$, $2H_2O$. This saccharine body is found in the muscular portions of the body, in the heart, brain, spleen, lungs, and kidneys, in hydated tumors, in normal and pathological urine, and in the vegetable kingdom, particularly in the Natural Order: Leguminosæ, such as peas, beans, also in some representatives of our materia-medica: digitalis and taraxicum. It forms large monoclinic crystals, generally in rosettes, soluble in water, insoluble in ether and alcohol. It is unfermentable, except in the presence of decomposing membranes, cheese and chalk, when lactous fermentation takes place with the formation of lactic, butyric, and carbonic acids. It is not decomposed by caustic alkalies, or weak acids, has no polarlizing effect on light, does not reduce metallic oxides, nor change color with potassic hydrate, and does not reduce cupric sulphate

[1] Read at the Practitioners' Club, Oct. 7, 1889.

in potassic hydrate; but is precipitated from solution by basic plumbic acetate and ammonic hydrate. If heated with a solution of cupric tartrate in potassic hydrate, no reduction follows as in the case of glucose; but a greenish solution results, which after a time precipitates, leaving the supernatant liquid the original blue color. If this be filtered the same reaction takes place. This last reaction, Tyson, in "Pepper's System," now claims is sufficient for its identification for clinical purposes. It can be readily made for purposes of study by the process of Vohl, who makes a watery extract of French beans, evaporates, precipitates, by alcohol, dissolves in water, and allows it to crystallize.

The significance—if there be any—of inosite in the urinary secretion, is not understood, it having been found under such varied circumstances in health and disease. Vohl called attention to it first, in diabetes insipidus; and here it had gradually displaced glucose, thus converting a mellituria into a inosturia; he also called attention to the increased quantity of this sugar, after the ingestion of large quantities of water. Senator, by its discovery, was led to believe that the diuretic action of this sugar might be held responsible for the very large excretion of urine in the same disease, but questioned the beautiful theory by uncertainty of its presence at all times. Strauss pointed out that on the flushing the kidneys of healthy subjects, with large quantities of water, this sugar could be found.

In diabetes, Neukoum and Gallois report this sugar in combination with glucose. Kutz failed to find it in persons who had been fed on a leguminous diet, which is contrary to my experience, for I have noticed it in a number of such, which had been carefully examined, but not in all. In various brain troubles, and in Bright's disease, the urine has also been found to contain this interesting compound. Leboulbain, Loomis, and Tyson consider the presence of inosite, in urines which contain glucose, and its increase as the grape sugar decreased, as a favorable prognostic.

Reviewing this subject, the following are the points to which I call attention:

1. That the greenish coloration and precipitate, often found in the examination of urine for glucose by Fehling solution, and by some good authorities said to be due to this sugar, is now known to be open to a different interpretation.

2. The substance which gives this reaction has been shown to be inosite or muscle sugar, another of the same group of sugars, which has been found in the human body under varied circumstances of health and disease.

3. The reduction of cupric oxide is necessary as a definite reaction for the determination of glucose, while this reaction never occurs in the presence of inosite.

4. The importance of the presence of glucose, as an indicator of disease, and the non-importance of inosite, makes it absolutely necessary that they should be differentiated at all times.

OLIVE OIL IN THE TREATMENT OF GALL-STONES.

BY THOMAS J. MAYS, M. D.

The formation of gall-stones occurs more frequently than most physicians suppose. It results in much pain, and is sometimes followed by fatal consequences. As, according to my experience, it is not very successfully treated, I conceive that anything which will tend to throw the least light on the therapeutics of this disease will be welcome, and therefore offer the following observations for the consideration of this Society, trusting that its members will see fit to make it a subject for special therapeutic investigation, in order to find out whether what I believe to be true of the action of sweet oil in this disease is based on a true or a false foundation.

Gall-stones are formed in consequence of faulty chemical change in the bile within the passages of the liver. These concretions form in masses which vary largely in number, size, and chemical composition. They may frequent any portion of the biliary passages, but are usually found in the gall bladder. By occluding the hepatic ducts they interfere with the passage of bile, cause it to be absorbed by the hepatic circulation, and in this way bring on the familiar jaundice which accompanies the disease, and by becoming impacted they may set up inflammation, degeneration, suppuration, and perforation in neighboring tissues.

The chief points of interest in the diagnosis of the disease are: The seat and nature of the pain, and the mode of its occurrence. It is by no means certain that a positive diagnosis can be made in all cases.

A patient may come complaining of a dull, heavy pain in the right hypochondrium, with a history of occasional paroxysms of pain in the same region, with a slight jaundice, indicated by a yellow tinge of the conjunctiva, and with an occasional shivering and fever —the indications are that he is suffering from biliary calculi. But if the patient is suddenly attacked with severe and agonizing pain in the same region, the centre of which is located directly over the seat of the gall bladder, and radiates to the right shoulder; and especially if the gall bladder is felt to be distended, and this without any elevation of temperature, the diagnosis of biliary calculi is almost certain. Fever is not invariably absent. Sometimes the premonitory symptoms of gall-stones simulate fever-and-ague on account of the occurrence of more or less marked rigors, together with a slight rise in temperature; and indeed it may be mistaken for the latter disease until its more active phenomena appear.

Speaking from my earlier personal experience in the treatment of this disease, I must confess that it was attended with the most discouraging results until I learned of the efficacy of sweet oil from my friend, Dr. Edward R. Mayer, of Wilkesbarre, Pa., several years ago; and I am glad to state that the hopes which were inspired by his accounts of the remedy have not been disappointed.

The investigations of Dr. Rosenberg are, so far as I know, the only ones in regard to its physiological action which have been made. They are described in a preliminary publication which appeared in *Fortschritte der Medicin*, in 1889. He established biliary fistulæ in dogs and observed that the administration of olive oil markedly increased the quantity of bile secreted; while at the same time it diminished its consistency.

The following cases illustrate the value of this agent. Mrs. A., 40 years old, had a sharp attack of pain in the right hypochondrium, December 29, 1889. This was preceded by rigor, fever and night sweats; and was followed by decided jaundice. Not having seen her during the attack, nor having had a similar pain before, I mistook her disease for malaria, and treated her with quinia, calomel, sodium, phosphate, acids, alkalies, hydrastine, podophyllin, leptandrine, etc., until February 11, when she felt very well, the jaundice had disappeared, the urine—which was loaded with biliary material—cleared up, the stools were of a normal color, and I ceased attending her. On the eighteenth of the same month I was called to see her again, and found her suffering with an intense pain in the right hypochondrium, with an evening temperature 100°, and the appearance of a tumor in the right hypochondrium. The pain was but imperfectly controlled by morphine and atropine. I at once began to give her sweet oil in dessertspoonful doses every four hours, and she improved from that time on, and has never had an attack since. In a few days after the beginning of the oil the enlarged gall bladder subsided, and it has given no trouble since.

A second case gave equally striking results. I was called to see Mrs. H., 45 years old, on the night of Aug. 10, 1889. I found her writhing in pain, which was indefinitely located over the whole abdominal region, but whose maximum intensity seemed to be confined more to the right side of the stomach. Large doses of morphine subdued her suffering somewhat. On closer inquiry I learned that the paroxysms had come on periodically for a number of years, and that she had been advised by her physicians to go abroad—which she did and remained there for several years. She was not entirely free from these attacks while there. She had returned only three weeks before this attack came on. I found on examination a perceptible dulness and swelling in the right hypochondrium. Sweet oil was prescribed in dessertspoonful doses every three hours, and this was followed by the most satisfactory results. In less than five days she said she was an entirely different woman. Her abdomen which was always hard, tense, and painful, became soft, her stool became natural in color and she has had not even an approach to an attack since.

The third case is that of a young man about 20 years old, who came to me with a tinge of jaundice in his conjunctivæ and skin, and with an ill-defined history of bilious colic during the previous three months. I placed him on sweet oil, and he has been free from his trouble since.

—Dr. Lauder Brunton, F. R. S., has accepted the offer of the Nizam of Hyderabad to proceed to India to repeat the experiments of the Hyderabad Chloroform Commission, and to further investigate the subject, for which purpose His Highness placed the sum of £1,000 at his disposal.

DIPHTHERIA FOLLOWING SCARLET FEVER.

BY L. S. WALTON, M. D.,
TULLYTOWN, PA.

On the morning of July 29, 1889, I was called to see a child, fifteen months old. I found the child had been vomiting freely, and was covered with a distinct scarlet rash, with a temperature of about 102°. On the following morning I found the child somewhat improved; but another member of the family, a little boy, seven years old, was suffering with all the symptoms which characterize a typical case of scarlet fever. The former case terminated in recovery in a few days, but the second child passed through a severe attack of the scarlet fever, and by the end of the second week the temperature had declined to almost normal, the tonsils had resumed their natural appearance, and desquamation had taken place freely, all symptoms pointing to a favorable termination.

On the morning of the fifteenth day, I found the temperature 104°, the pulse 104; and the tonsils were enormously swollen and covered with diphtheritic membrane. The case now presented a very unfavorable prognosis. I prescribed the following mixture:

℞ Tinct. Ferri chloridi. . . . . ℥iii
Potass. chlorat. . . . . ℥ii
Quiniæ sulph. . . . . ℥ss
Aquæ . . . . . q. s. ad ℥iv
M. Sig. One teaspoonful every 2 or 3 hours.

Locally I applied a strong solution of tannin, with a large camel's hair brush, once every hour. The above remedies were continued throughout the disease, occasionally increasing or diminishing the quinia as indicated. Brandy was also administered freely. As the case progressed the temperature fluctuated between 103° and 104°, until the tenth or twelfth day, when the temperature began to decline. The tonsils began to decrease in size and the diphtheritic deposit began to soften, and by the end of the fourth or the beginning of the fifth week convalescence was established. Notwithstanding the patient passed through two of the most dreaded of all diseases, a complete and perfect recovery followed, leaving no trace of renal nor cardiac trouble. This case is of interest from a therapeutic point of view. Having used many of the new remedies that have been suggested in the treatment of diphtheria, I have found nothing as satisfactory as the above described remedies.

REPORTS OF CLINICS.

BELLEVUE HOSPITAL.

MEDICAL CLINIC — PROF. BEVERLY ROBINSON.

Stricture of the Œsophagus.

Case I.—A man, 43 years old, single, a tailor, native of Germany. He has been a hard drinker. Twenty years ago he had a hard chancre, followed by secondary symptoms, for which he was under treatment in Germany for five years. Since that time he has been treated at the different Dispensaries for rosaceous acne, rosacea, chronic pharyngitis and nasal catarrh, and gastric catarrh. He entered the Charity Hospital for trouble in the throat. For one year he has suffered from painful and difficult swallowing and inability to swallow solid food unless it was chopped very fine. He says he cannot talk for any length of time without losing his voice and being unable to speak above a whisper. He occasionally vomits his food, if taken in large pieces, immediately after ingestion. On no occasion has he vomited blood, coffee-ground or frothy material. He has lost very little flesh and suffers from no other symptoms.

The patient is given a glass of water to test his ability to swallow. He pauses between each mouthful and forcibly bears down as the liquid passes from his mouth. None is regurgitated. There is no coughing or choking. He places his hand at a point just below the cricoid cartilage, to locate the spot where he believes there is obstruction, and says he has to "press down" to force his food beyond this point.

His dysphagia is growing worse, and his condition is a serious one. Suffice it to say, thorough examination into his history proves him to be syphilitic. This being granted, what other condition have we here? First, has he laryngeal trouble, such as tubercular, syphilitic or cancerous? Probably not, from the fact that he easily swallows liquid and has difficulty with solid food. The reverse is the rule in laryngeal trouble. It is by no means a certain sign, however; but a very strong inference. And, besides, choking and coughing is absent. Further careful laryngoscopic examination is negative. Next,

may there be paralysis of the pharynx? The patient shows no palsy, and gives no symptoms of mental trouble, or paresis, and inspection shows that the act of swallowing is sufficiently vigorous. Examination of the throat is also negative.

Has he then stricture of the œsophagus? And is it spasmodic, traumatic, carcinomatous, or syphilitic? It is not spasmodic. On questioning him, he says deglutition is not at all affected by nervous influences; and besides this is a condition almost always found in the female. Furthermore the bougie settles this fact. The patient has never swallowed any caustic fluid nor received any injury from lodgment of wounding substance in gullet, and so does not give a history of simple traumatic stricture. It is probably not carcinomatous, because he has never spat blood, and manipulation with the bougie is not followed by blood, and there has been no vomiting of froth or frothy matters. Examination does not reveal any tumor or enlargement in the neck.

On passing a medium sized bougie it is arrested at about eight inches from the teeth, a point corresponding to lower border of cricoid cartilage. On using a smaller instrument, then a still smaller one, both are arrested at the same spot. It has been determined at a previous examination that the stricture is about one inch in length and is dilatable, and the patient experienced some improvement after the operation.

The diagnosis of probable syphilitic stricture is made; may be from a gumma, may be from the scars of old ulcerations.

The treatment should be the daily passage of bougies, and instruction of the patient to pass them himself later on every second or third day, and together with the internal administration of mercury and iodide of potash. Thus the man may live for many years.

I advise you to study every case by itself, remembering that you may in practice find diseases which differ much from the form described in the text-books. Each patient may present a peculiar aspect of disease; I have never seen two patients and two diseases exactly alike.

Brain Syphilis.

Case II.—A man, 38 years old, widowed, a native of United States, and a carpenter. He denies that he ever had a venereal sore. Eleven and one-half years ago he had a suppurating bubo, and eleven years ago an eruption all over the body, but no other symptoms that might be called "secondary." He was well up to six years ago, when he had this attack. He went to bed well and awoke next morning with paralysis of the right side and aphasia. He does not remember to have lost consciousness. He had no convulsions. He was under treatment for one year; and then went to work. Two years after the first attack he had another—this time on the left side; and similar to first stroke. He regained his speech after six weeks and his power of movement in five months.

Examination shows some weakness on the left side and decided loss of power on the right side of the face and limbs, with dragging of the right leg and a characteristic hemiplegic gait. His sensation is good; his mind clear; and his appetite is good. His bowels are constipated; his urine has a specific gravity of 1.008 and shows nothing abnormal.

He has been under treatment with iodide of potash in increasing doses. This is to be continued, together with strychnine, electricity and nutritious diet. The differential diagnosis between embolism, thrombosis, hemorrhage, and the existence of arteritis is impossible. Certain points in the case lead us to one view, some to another; but we cannot hold any one view with positiveness. The course of the malady and the absence of loss of consciousness would make me favor the idea of embolism. I saw a case a few days ago in a private patient who was stricken in what appeared to be an apoplectic attack in Jersey City and was removed to the City Hospital. He was suffering from palsy of one side and convulsions of the other. Knowing him to be syphilitic, I so informed his attending physician. I learn to-day that the patient is rapidly improving under anti-syphititic treatment.

Dilatation of Heart.

Case III.—A man, 40 years old, a miller by occupation for the past thirteen years. He has always worked at night. He does not drink, but is a heavy smoker. Has always enjoyed good health, and has gained fifty-six pounds in weight in the last few years. Three months ago he had a sudden attack of "goneness" over the region of heart. He grew pale and almost fell, and thought he was going to die; but he did not lose consciousness. He had no vomiting or headache, no disturbance of vision.

He had vertigo for some minutes and felt weak for the rest of the day. He had another attack two weeks ago and another to-day. He has not been at work for some time, by advice; but he feels able to go, and says he seems well. He has no palpitation or dyspnœa.

Examination reveals a blowing murmur at the apex of the heart, and shows the heart sounds to be very indistinct and the heart's action to be very weak.

The patient is suffering from dilated heart, with probably one of two conditions: either a fatty degeneration, or a fibrous myo-carditis, which cannot be learned during his life.

The prognosis is decidedly bad. Of this I am very sure. He may drop dead at any moment. In most cases it is best not to acquaint the patient with this fact; for if we do the dread hangs over him and perhaps may shorten his life. But relatives should be informed fully, and the patient should be made to stop his business and give up bad habits. In this case smoking must be stopped—gradually, not suddenly; and a course of digitalis, iron and compound tincture of cinchona promises the most.

LETTER FROM BERNE.

O'Dwyer's Intubation in Acute Laryngeal Stenosis.—The Influence of General Massage on the Composition of Urine.—The Effects of Abdominal Massage on Assimilation and Metabolism.—Abdominal and Lumbar Massage as a Genuine Diuretic.

BERNE, September 20, 1889.

Dr. O. Guyer, house physician to the Hospital for Children, in Zurich, reports twenty-seven cases of diphtheria in which O'Dwyer's intubation was performed on account of acute laryngeal obstruction, with thirteen (48 per cent.) recoveries and fourteen (52 per cent.) deaths. In all of the cases, the stenosis was so great that the only chance for saving the patient's life was in performing either tracheotomy or incubation of the larynx. The age of those that recovered varied between eight months and seven years, six patients being less than four years old. The age of the children that died ranged between one and nine years, seven being under four years of age. In eight of the fourteen fatal cases, tracheotomy was performed after intubation had failed. In eleven of the fourteen, death was caused by extension of the morbid process to bronchi; in two by supervening pneumonia, and in one by consecutive nephritis developing after the child had recovered from diphtheria. In all the fatal cases, cloudy swelling of the renal epithelium was found at the autopsy; in none could any injury to the larynx or trachea by intubation be detected. Pointing to the results (which are even better than those obtained by Drs. Dillon Browne and Francis Huber, whose respective series show only 27 and 40 per cent. of recoveries—*vide* the MEDICAL AND SURGICAL REPORTER, April 27, 1889, p. 516, and Feb. 2, p. 146), Dr. Guyer emphatically states that "Dr. O'Dwyer has done a great service to suffering humanity by introducing his method which, most decidedly, constitutes an essential advance in the treatment of laryngeal obstruction." True, he does not expect that intubation will ever supersede tracheotomy altogether, but he firmly believes that the former may limit the necessity for the performance of the cutting operation. Hence he insists that the tracheotomy bag should invariably contain all the intubation appliances. According to the author's personal experience, intubation may sometimes fail to bring relief to the obstruction where the cause of the latter lies above the false vocal cords, as is the case when there exists an intense swelling of the ary-epiglottic folds or of the tonsils and soft palate, accompanied by nasal obstruction. In the presence of such conditions, tracheotomy may yet be successful, after intubation has failed to give relief. Further, in exceptional cases tracheotomy may afford the only means for saving the child's life by a direct aspiration of bronchial pseudomembranes. Hence, the author lays down the following general rule: Given a case of extreme acute laryngeal stenosis, perform intubation at once; if no relief follows within a reasonable time, and if the symptoms point to bronchial diphtheria, do tracheotomy. Speaking of advantages of intubation, in comparison with tracheotomy, Dr. Guyer lays stress on its bloodlessness, simplicity (in regard to both the performance and the after treatment), its complete freedom from such risks as septic infection or consecutive hemorrhage, etc. As a rule, the tube can be safely and

conveniently removed from the child's larynx on the fifth or sixth day.

The author's statements are fully endorsed by a colleague of his, Dr. W. von Muralf, the Chief of the Zurich Diphtheritic Station for children.

In order to study the influence produced by massage on the systemic metabolism in healthy man, Dr. H. Keller, of Rheinfelden, has carried out a series of experiments on himself. His daily dietery consisted of 500 grammes of chopped meat (tenderloin), 500 grammes of unsalted white bread, 100 of fresh butter, 2 of salt and 1,500 of water. Massage of the abdomen and all four limbs was performed daily for three-quarters of an hour by Dr. Mueller. The urine (but neither feces nor the food) was analyzed. The author has arrived at the following conclusions: 1. The bodily weight remained unaltered. 2. Massage does not possess any diuretic action (in the old-fashioned sense that it does not increase the amount of urine voided). 3. But it gives rise to an increased excretion of nitrogen. This, however, should be attributed, not to any increase in the decomposition of proteids, but simply to an intensified washing out of nitrogen from tissues in virtue of massage stimulating the circulation of blood and lymph. 4. The excretion is correspondingly augmented. 5. The elimination of chlorides and phosphoric acid steadily increases from day to day; and this must also be explained in the way indicated above. 6. The excretion of lime is, on the whole, similarly augmented, but is subject to considerable daily variations. 7. Therefore, massage of the whole body manifests a distinct influence on the chemical composition of the urine, increasing the elimination of nitrogen, sulphur, phosphorus, chlorin and calcium compounds. 8. The rise should be attributed, on one side, to increased absorption from the digestive tract, and, on the other, to increased energy of the metabolic processes. The first is induced by the mechanical action of massage on the abdomen; the second by the stimulating effects of massage on cell-activity, and by its acceleration of the blood supply as well as the reflux of the blood and lymph.

An important contribution to the biology of massage has been recently published by Dr. Boris I. Kïanovsky, house physician to Professor V. A. Manasseïn's clinic, in St. Petersburg. To elucidate the effects of abdominal massage on the assimilation of nitrogen and fats of food, and on the nitrogenous metabolism, he has undertaken nine most careful experiments, each of from 12 to 18 days' duration, on as many healthy subjects—himself and 8 medical students. As in all Russian experimental researches concerning the metamorphosis, the systemic changes were invariably determined by chemical analysis of the urine, the feces and every food-article ingested (and not of the urine alone, as in Dr. Keller's case), because a correct insight into the organic processes in question can be obtained in that way only. The essential results obtained by Dr. Kïanovsky may be summarized briefly as follows: 1. The assimilation of nitrogenous constituents of food invariably improves under the influence of abdominal massage, the increase varying from 1.4 to 5.762 per cent. 2. The assimilation of fats is also augmented, at a rate ranging from 0.657 to 3.242 per cent. 3. The nitrogenous metamorphosis rises from 0.6 to 10.9 per cent. 4. All these facts may be accounted for in this way. Abdominal massage improves the muscular and nervous tone of the body in general, and of the abdomen especially. It produces a stimulating action on the systemic circulation, especially in the abdominal cavity, as well as on the gastro-intestinal tract and other abdominal organs. This leads to an increase in the secretion of all digestive juices, and in intestinal peristalsis, the general result being better absorption and a better assimilation. 5. Appetite invariably improves. 6. Notwithstanding the increase in the nitrogenous metabolism, the body's weight as a rule invariably rises. 7. The *séances* are invariably followed by a pleasant sensation of wholesome fatigue and drowsiness. 8. In some persons, an incomplete erection of the penis occurs during the *séance*, and disappears shortly after it. In six out of nine persons the *séances* produce a desire to pass urine. Dr. Kïanovsky adds that thoracic massage, when performed during attacks of bronchial asthma, shows a distinctly sedative effect on the symptoms; and that general massage affords a useful adjuvant means in the treatment of poisoning by morphium.

Another able and substantial contribution to our knowledge concerning the biological effects of the mechanical method in question has been lately brought forward by another house physician to Professor Manasseïn's clinic, namely, Dr. Alexander A.

Polübinsky, whose investigations throw some light on the influence of abdominal and lumbar massage on the action of the kidneys. As far as the lumbar region is concerned, the manipulations consisted in circular, longitudinal and transverse (grasping) and pretty energetic frictions from the angle of the scapular to the buttocks. The abdominal massage was limited to *effleurage*, *massage á friction*, and *pétrissage* along the course of the colon. The *séances*, each of one-half hour's duration, were repeated once or twice daily. The number of persons experimented upon was ten, two of them being perfectly healthy, four neurasthenic, three convalescent from sciatica or pneumonia, and one suffering from bronchitis. The outcome of Dr. Polübinsky's observations is exceedingly interesting. He has found that: 1. Abdominal massage very considerably augments the amount of the urine passed by the patient during the next four hours—in fact the four hour quantity of urine sometimes is three times as large as the daily amount in a non-massage day in the same person, all other conditions being equal. 2. At the same time it very markedly raises the proportion of solid constituents, urea and total nitrogen of the urine closely tallies with the statement of Drs. Mary Putnam and V. S. White, who similarly observed an increased elimination of urea in the urine voided during four hours after the sitting of general massage. 3. As to lumbar massage, it apparently does not show any marked influence upon the quantity of the urine, but, on the other hand, it very considerably increases the amount of urea and total nitrogen in the urine, sometimes even to a larger extent than abdominal massage does. This increase, however, proceeds very gradually and is still marked in the urine voided many hours after a *séance*. 4. In view of these facts lumbar and abdominal massage may be justly regarded as a "genuine diuretic" measure and may be employed as such.

Under the denomination of a "genuine diuretic," the author, following Professor Manasseïn's teachings, understands, "such means as can eliminate from the system an increased (comparatively with the supply) percentage of *all* constituents of the urine, and not of water alone, without simultaneously decreasing the pulmonary and cutaneous losses." As to the latter, they are even increased by massage, as Dr. Stabrovsky's researches have unmistakably proved and explained in his *Inaugural Dissertation, St. Petersburg*, 1887. Dr. Polübinsky's highly instructive paper may be found *in extenso* in the *Vratch*, No. 22, 1889.

VALERIUS IDELSON.

PERISCOPE.

Hygienic Reform in Spain.

At a recent meeting of the Sociedad Española de Higiene, the President, Señor Martinez Pacheco, bewailed the apathy both of the Government and of the public in Spain with respect to sanitation. He mentioned several parts of the country in which malaria still prevailed, and others in which pellagra and leprosy were extending their ravages. The Society has formulated an appeal to the authorities, calling for the establishment of a public system of disinfection in every town of any importance, and the rigorous enforcement of the measures for that purpose approved of by the Congress of Hygiene held at Vienna. It was also urged that a transport service should be organized in every town for the removal to hospital of persons suffering with contagious disease. The Society further asked for the establishment of a proper drainage system in towns; that latrines and cesspools be abolished; and that every house be provided with drains properly trapped, and with pipes disconnected from the sewers. Other desirable reforms are indicated, and it evidently will not be the fault of the Society of Hygiene if a sanitary millennium is not soon inaugurated in Spain. We fear, however, that it will take the Society a long time to educate public opinion in that romantic but unsavory country up to its own level.—*British Med. Journal*, July 6, 1889.

Opening Buboes.

Dr. J. P. H. Boileau states in a letter to the *British Med. Journal*, July 6, 1889, that the best method of opening a bubo is a matter of much greater importance than at first sight appears, and especially to the military surgeon, who has so many of them to treat. He believes that a very considerable reduction of his "constantly sick" would be the result of a procedure different from that which now prevails.

It is now, he says, some four and twenty years since he abandoned the free incision by which he was taught to open a bubo, a method of opening which is still very generally adopted, apparently orthodox, and perhaps, in civil life, necessary. For he has many years invariably opened a bubo by a mere puncture with a narrow-bladed bistoury, and he is so very well satisfied with it that he intends to continue the practice. By adopting this method the most odious spectacle, "an open bubo," is avoided, as well as the reproach of a protracted cure; but not in all cases by any means, for sinuses will form that must be opened up, and the consequence of neglect, or a vitiated state of constitution, must be dealt with. It is necessary to observe that to obtain the best results a bubo should be opened at the proper time; not too soon before a sufficiency of morbid deposit has broken down, nor too late when the vitality of the tissues may have become impaired. The experienced operator chooses the right time, which is probably a very few days after the presence of pus has been diagnosticated. The small opening made by the bistoury will often be found closed the following day; it may be reopened by a blunt-pointed probe if necessary. The puncture, he says, is much less painful than the free incision, and it of course has the advantage of leaving but a very small mark, whilst it has no disadvantage, as it can at any time be converted into as long an incision as may be thought necessary. He is certain that the opening of a bubo by a free incision, instead of by puncture, often extends the duration of a case from days to weeks, or from weeks to months.

Shuttle Pulse.

Dr. C. H. Hughes in the *St. Louis Med. and Surg. Journal*, Oct., 1889, says:

There is a peculiar pulse which I have sometimes felt but never without a shudder, when felt in the radials of those whom I have loved—never without grave prognostic impression whenever perceived in any patient. Have you ever felt it, reader, and if you have, what has it signified to you? I mean the shuttle pulse, as I would call it; a pulse in which the pulse wave passes under your finger as if it were floating something solid as well as fluid—that something passes along the blood current under your finger like the weaver's shuttle through the loom. I have felt it in cases only where the blood was hydræmic and a local rheumatic inflammation existed or had recently existed within the heart.

I have called it the "shuttle" pulse because I can liken it to nothing else and because the impression it makes suggests the name. Have you felt it under these circumstances, or any other, and do you know a better name for it? If you have ever felt this pulse, did you ever know of a patient recovering after its appearance? Did you ever know a patient after its appearance to escape the consequences of embolic closure of vessels? To me it is the pulse of fibrinous coagula going the rounds of the circulation. Its portent has ever been evil. It is a pulse of dark prognosis and painful memories—the pulse of impending death in part or whole. I think I have never known a patient to live after such a pulse has been detected. It is the pulse of fatal rheumatic endocarditis or endo arteritis and its sequent and associate anæmia and emboli.

Angina Pectoris Caused by Compression of the Sympathetic Nerve.

From the majority of dissections, it has been found that the cause of angina pectoris is in all probability an irritation of one of the three nerves which assist in respiration: the phrenic, the vagus, and the sympathetic nerve; and, as a rule, the seat of the trouble is in the thorax. An exception to this rule was observed in the following case, which is reported in the *Deutsche Medizinal Zeitung* for August 1, by Dr. Humbert Mollière.

The patient, a man, 59 years old, who for ten years had been troubled with a cough, and two months before had had profuse diarrhœa with pain in the abdomen, and was greatly emaciated. In conjunction with the cough, he was also troubled by frequent and long-continued attacks of angina pectoris of a most severe form. Upon physical examination he was found to be suffering from bronchial catarrh, but no abnormal condition of the abdomen was found. For the next few days the attacks became much more frequent, and the patient rapidly lost strength and finally succumbed while suffering from an acute attack of the angina, in spite of all that was done to relieve his sufferings.

At the autopsy, it was found that the mesenteric and the prevertebral nerve

ganglions had undergone cancerous degeneration; and that portion of the sympathetic nerve between the stomach and the pancreas was surrounded and compressed by a carcinomatous mass of lymphatic glands.

Emphysema was found in both lungs, as well as secondary carcinomatous nodules. The bronchial and pulmonary nerve ganglions were entirely intact, the ends of the vagus and phrenic nerves extended to the solar plexus. This last was compressed in such a way, that it was undoubtedly from this cause that the angina had proceeded. It is most probable also that in an analagous manner an irritation of the ends of the sympathetic nerve, which are in the mucous membrane of the bowels, would also give rise to angina pectoris.

Death After Taking Nitrous Oxide.

A painful death occurred in a dentist's house in Edinburgh recently. An old lady, of over 75, visited a dentist for the purpose of having a tooth removed for disease of the antrum. The operation was successfully conducted with the aid of nitrous oxide, but, while the cavity was being treated, the patient was observed to lapse into a state of unconsciousness. All efforts at resuscitation proved ineffectual and, before further medical advice could be obtained, death had resulted. It appears that the patient had suffered previously from weak cardiac action.—*British Medical Journal*, Oct. 12, 1889.

Trinitrin in the Treatment of Arterio-Sclerosis.

Huchard recommends a one per cent. alcoholic solution of nitroglycerine in the cases of arterio-sclerosis in which the preparations of iodine are not well borne. The average dose in which the remedy can be given, without the fear of bad secondary effects, is from ten to twelve drops a day, in five or six portions. The dose of twenty drops should not be exceeded, as with this quantity decided supra-orbital pains occur frequently. In order to prevent the patient from becoming accustomed to the remedy, Huchard allows the patients to take the preparations of iodine for twenty days each month, and trinitrin for the remaining ten days. If it is desired to administer the trinitrin in solution, a mixture can be made of thirty drops of a one per cent. solution of nitroglycerine and nine and a half fluid ounces of water, of which from four to eight tablespoonfuls may be given daily. Where a rapid effect seems desirable, as, for example, in angina pectoris, Huchard recommends the subcutaneous injection for two or three syringefuls of the following solution:

Alcoholic solution nitroglycerine (1 per cent.)	40 drops
Distilled water	150 "

Iodide of potash can also be combined with trinitrin:

Iodide of potash	5 drachms
Solution of nitroglycerine (1 per cent.)	30 minims
Distilled water	9½ fl. oz.

M. Sig. Two tablespoonfuls daily.

—*Wiener med. Presse*, Sept. 15, 1889.

Epidemic Nephritis in Children.

Dr. Stefano Mircoli, of Bologna, according to *Schmidt's Jahrbücher*, September 15, 1889, has observed fourteen cases of nephritis occurring epidemically, in the course of two months, in children varying from three to ten years of age. A very fine disease-picture was presented, unassociated with affections of the skin and other organs. It began with high fever, which fell after four or five days; then large albuminuria and tense œdema first appeared. Improvement occurred from the tenth to the fifteenth day, the disease never becoming chronic. Three of the children died. Acute redness and swelling of the cortex of the kidney were found in the case of the first child, which died on the fourth day of the disease. The kidney exhibited, on microscopic examination, the typical appearance of embolic septic nephritis. Cocci lay in heaps in the small vessels, in the glomeruli or in the connective tissues, and in the uriniferous tubules; the epithelium of the latter exhibited corresponding destruction, especially granular. The connective tissue was hypertrophied. In the cases of both the other children which died on the tenth and fifteenth day of the disease respectively—large white kindeys were found at the autopsy, but no coci. Mircoli thinks they had been present, but had died. Abundant albuminates were found in the uriniferous tubules.

Some Useful Remedies for Sleeplessness.

The following useful formulæ for the administration of hypnotics were given in a recent number of the *Deutsche med. Wochenschrift.*

℞ Amylen. hydrat. . . . . grs. cv
Aquæ destil. . . . . f℥ii
Ext. Glycyrrhizæ . . . . . ℥iiss
M. Sig. Half to be taken in the evening before going to sleep.

℞ Amylen. hydrat. . . . . ♏lxxv
Mucil. Acaciæ . . . . . f℥v
Aquæ destil. . . . . f℥iss
M. Sig. For a clyster.

℞ Chloralis . . . . . ℥i
Aquæ destil. . . . . .
Syr. cort. Aurant. āā . . . . . f℥x
M. Sig. Dose, one to two tablespoonfuls.

℞ Chloralis . . . . . gr. xlv
Potass. brom. . . . . gr. lxxv
Aquæ destil. . . . . f℥iii
Syr. Aurantii . . . . . f℥iss
M. Sig. The third part to be taken once, in the evening.

℞ Lactucarii . . . . . gr. ix
Gum. Acaciæ . . . . . ℥i
Aquæ destil. q. s. fiat emulsio . . f℥vi
Adde :
Syr. Aurantii . . . . . f℥i
M. Sig. A tablespoonful every hour.

℞ Paraldehyde . . . . . f℥i—f℥iss
Aquæ destil. . . . . f℥iii
Syr. simplicis . . . . . f℥iiss
M. Sig. Half to be taken once.

℞ Phenacetin . . . . . gr. viiss—xxiii
M. Dispense doses tales No. VI.
Sig. One powder in the evening.

℞ Sulphonal . . . . . gr. xv—xxx
Divide in 5 equal parts.
Sig. One powder in *cachets* in evening.

℞ Urethan . . . . . f℥i
Aquæ destil. . . . . f℥x
Syr. Aurantii . . . . . f℥v
M. Sig. To be given in tablespoonful-doses at intervals of one-half to one hour, according to desired effect.

—*Wiener med. Presse,* August 11, 1889.

The Toxic Effects of Coffee.

In the *Therap. Monatshefte* for March a case is recorded of poisoning with coffee. A strong and vigorous man, in the absence of his wife, prepared for himself some coffee. Ignorant of what quantity to use, he made the infusion very strong, using for the purpose two cupfuls—about two ounces and a half of the ground berries. Two hours and a half after drinking the infusion vertigo supervened; this was followed by severe headache and tremors, limited at first to the part, and then becoming generalized. To these symptoms were subsequently added flushing of the face, great palpitation, nausea, and vomiting. A practitioner saw the patient about six hours after the ingestion of the coffee, at which time the most prominent symptom was generalized and intense tremors, especially noticeable in the hands and face, in the latter instance rendering the patient's speech very difficult to comprehend. The face, moreover, was deeply flushed, and the forehead bathed in perspiration. There was much precordial pain, but the heart sounds were normal. Pulse 100, very full and bounding. The patient micturated frequently. Six drachms of bromide of potassium were prescribed in two doses, after which sleep was induced, and the symptoms gradually declined, the man being convalescent in three days.—*Medical Press and Circular,* June 12, 1889.

The French Surgical Congress.

The fourth French Surgical Congress was opened on October 7, 1889, in the amphitheatre of the Faculty of Medicine of Paris, under the presidency of M. Larrey, who succeeded M. Verneuil. About one hundred surgeons, members of the Congress, were present. The President delivered a short address, after which the Secretary-general, Dr. Pozzi, read a list of the names of the officers of the Congress.

Tænicides for Children.

Descroizilles and Duchenne suggests the following formulæ for the administration of tænicides to children (*London Medical Recorder,* June, 1889):

℞ Ext. Felicis Maris fl. . . . f℥ss—f℥iii
Ess. Anisi . . . . . ♏x
Aquæ Menth. pip. . . . . f℥ss
Aquæ Anthemidis . . . . f℥i
Syrupi,
Syrupi Aurantii cort. āā . . f℥vi
M.

℞ Ext. Felicis Maris fl. . . . f℥i
Hydrarg. chlor. mitis . . . . . gr. vii
Sacchari . . . . . ℥ii
Gelatine q. s. to make a jelly of a proper consistency.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

CONTAGIOUSNESS OF LEPROSY.

From time to time during the past year, we have published different communications —abstract or editorial—bearing upon the subject of leprosy, which has been discussed very freely in this time. The readers of the REPORTER are aware that in our opinion this disease ought not to be spoken of as contagious in the ordinary acceptation of this term, although it appears possible that it may be "communicatable" from one individual to another under peculiar and extremely rare circumstances. It is known, of course, that a certain number of pathologists are strongly convinced that the disease is contagious, but we doubt that the profession in general will fail to notice the great difficulty they find in bringing forward even a very small number of cases to justify this opinion, although leprosy is a disease which is to be found in almost every part of the world, and if it were contagious in any such sense as are other diseases to which the term is applied, the examples of contagion ought to be numerous and easy to discover.

It is interesting to note that Dr. George Dock, Professor of Pathology in the Texas Medical School, at Galveston, has recently reported two cases of leprosy, which seem to furnish important evidence in this connection. Dr. Dock is a pathologist thoroughly competent to express an opinion on this subject, and it goes for much when he states, after all he has studied in these cases, that "Contact alone, even when intimate and long continued, cannot be a source of danger, and that other factors, as predisposition (of which we know nothing) and solutions of continuity of both bodies, must play the most important part." The cases, which he describes admirably, were remarkable ones. Two men for a period aggregating thirteen years or more, associated with their fellows, and lived in the most intimate relations with their wives and children, and yet, so far, no other case of the disease had been acquired from them.

It seems impossible to determine the important question as to the contagiousness of leprosy in such a way that the conclusion shall be accepted fully, by both contagionists and non-contagionists; but from a purely judicial standpoint, we feel convinced that those who make the most of such evidences as exist that this disease may be conveyed from one individual to another, ought to select some other word to express their belief than that which is applied to the communication of small-pox, scarlet fever, and other diseases of the same kind. This not only is important from a scientific standpoint, but it is also of the greatest importance from a hygienic and social standpoint; for a true knowledge of the nature of this disease would probably prevent great and needless hardships to patients suffering with it, and—as is well understood in this city—might come very opportunely between conscien-

tious and thoroughly competent practitioners of medicine, and an unreasonable and misguided community.

OPEN AIR TREATMENT OF CONSUMPTION.

At the last meeting of the Climatological Association, Dr. Henry J. Bowditch read a most interesting paper on open air travel in the treatment of pulmonary consumption. The text of the paper was based on the history of his consumptive father who succeeded in restoring his shattered health by taking a long journey in a one-horse chaise through New England. When he started on his trip he was very much reduced, and he had hemoptyses before he had traveled twenty-five miles. He was resolute, however, and pushed forward, and after that he had the pleasure of noting an improvement in his health on every succeeding day. He drove for thirty days and during that time passed through one hundred and thirteen towns, journeyed over seven hundred and forty-eight miles of wagon-road, and returned to his home much better than when he left it. Afterwards a permanent cure was effected by walks of one and a half to two miles, taken three times daily during the remaining thirty years of his life. He died at the age of sixty-five, from cancer of the stomach, the apex of one lung showing an old cicatrix, but otherwise both lungs were normal.

This case presents a most instructive lesson to us, inasmuch as it points out at least one method by which consumption may be successfully circumvented. There is no question that pulmonary consumption is a constitutional disease, which, as was suggested in an Editorial in the REPORTER, September 7, 1889, can be rationally treated only by economizing the bodily forces—which means a diminution of the outgo, and an increase of the bodily income. The outgo is the waste caused by the fever, loss of flesh, anorexia, insomnia, night-sweats, and cough. So long as this equals, or outbalances the bodily income derived from the food, air, etc., so long will the patient's condition remain the same, or decline. Exercise is likewise a drain on the bodily resources, and just so long as this fatigues, just that long should the patient be restricted as closely to absolute rest as possible. If Dr. Bowditch's father had chosen to walk, instead of remaining practically quiet in his carriage, as he rode through the country, it is exceedingly doubtful that his mission would have been crowned with the same success. The exercise which brings tone and trength implies the pre-existence of strength, and this if properly used and nourished will grow and accumulate. But the consumptive is in a chronic state of exhaustion, and has no strength, or very little, to spare for exercise. A short walk, a few forced respirations, or swinging of the dumbbells, will often utterly sap his strength. Whether by instinct, or by conscious effort, it is very clear that Dr. Bowditch's father struck the proper mean in this matter. He waited until he was sufficiently strong to bear physical exercise, and then its application was followed by the happiest results. The wisdom of his course is also approved by the practice now in vogue of treating consumptives in the lying or sitting position in the open air, or of shutting phthisical patients up in a sailing vessel which is bound for a distant port.

Although treatment of this sort is carried on in the open air, we are not disposed to credit all the good that comes from it to fresh air alone. Indeed it is probable that the breathing of a vitiated air is less harmful than is generally believed. The inhabitants of cold countries, like those of Iceland, Greenland, and Lapland, live in crowded underground hovels, and breathe an atmosphere loaded with a filth that is exhaled from the body, yet these people are practically free from pulmonary consumption; while those people who live in the tropics, and who have a bountiful supply of fresh

air streaming through their houses day and night the whole year round, do not by any means enjoy an immunity from this disease.

While not in the least desiring to underrate the value of good ventilation we cannot help thinking that when stripped of all its paraphernalia the treatment of pulmonary consumption in its most serious stage is not so much a question of physical exercise and pure air as it is one of real physiological rest of both body and mind. A consumptive must be removed from his occupation; his activity must be bridled; his habits must be revolutionized; his fever must be reduced; his appetite must be restored, and his sleep must become restful. A game of chess, checkers, or whist, the reading of a novel, a ride through the country, the monotony of an ocean voyage, or a trip to the mountain, are all to be reckoned, provided they weary neither body nor soul.

TREATMENT OF TETANUS.

Cases of recovery from tetanus are rare enough to be deserving of careful study, and great interest attaches to the report of such an occurrence in the *Lancet*, Oct. 12, 1889.

The patient was a boy, seven years old, who developed symptoms of tetanus after receiving a burn upon the leg. He had well-marked spasms of the glottis and opisthotonos. The spasms came on very often, and during their continuance the heart beat tremulously and the whole body was bathed in perspiration. A hypodermic injection of $\frac{1}{100}$ grain of salicylate of eserine every three hours, was ordered, and a mixture, containing ten grains of bromide of potassium and half a drachm of syrup of chloral hydrate, in half an ounce of water, was given every three hours, the medicine being given an hour and a half after each injection. The diet was beef tea and milk. Under this treatment the patient did well, getting a good deal of sleep for forty-eight hours, when the dose of eserine was increased to $\frac{1}{60}$ grain. Nine days later the use of the bromide and chloral mixture was discontinued and the eserine was injected only three times a day. At this time the rigidity of his abdomen still continued, but he could open his mouth widely. There were a few moist râles at the bases of both lungs. The next day the risus and trismus were almost gone; the temperature was 98.6°; the pulse 86; the respiration 19. Ten days later the injections of eserine were discontinued.

The time during which this treatment continued was over three weeks, and the cure seems to have been brought about by the prolonged use of the remedies: Eserine with chloral and bromide of potash for eleven days, and eserine alone for twelve days more.

Mr. J. R. Raywood, who had the patient under his care, attaches the greatest importance to the use of the eserine. Its action, he says, was most marked; for although the bromide and chloral may have assisted to recovery, yet these drugs had no direct control over the spasms. Whenever a dose of eserine was omitted the muscular spasms were stronger and more frequent, and no relapse occurred when the bromide and chloral were discontinued.

The management of cases of tetanus is so troublesome and usually so unsuccessful that it is pleasant to be able to record even single cases in which recovery has taken place. Our readers are quite aware that the remedies used in the case just described are not new, and they may even have employed them with much less fortunate results. None the less it is worth while to study the details of the case carefully, in order to see if it may not furnish useful suggestions for the management of this dreadful disorder.

SMALL PLAGIARISMS.

Once or twice lately we have adverted to the matter of plagiarism in the medical journals and have called attention to rather heinous examples of it. But there remains a species of plagiarism which deserves a

word, because—while less serious in some senses—it is a more frequently occurring breach of courtesy and morals. This is the practice of stealing abstracts and translations from other journals, which is usually indulged in by obscure publications, but which at times is not too small for journals of which better things might reasonably be expected. An example of this is to be found in the *Journal of the American Medical Association* for October 26, which contains a short article that was translated in the office of the *Medical News,* and published in its issue of September 14. This has been appropriated, word for word, without naming the source from which it was derived and in a way calculated to convey the impression that it was a translation made in the office of the Journal of the Association. Such a proceeding is never admirable and it is especially to be regretted that it appears in a journal which represents the American Medical Association, and which ought to set an example of austere virtue to the other journals of this country.

OBLIGATORY ATTENDANCE BY PHYSICIANS.

The close watch and rigorous supervision which are exercised in most European countries over all trades and professions have many advantages, but they have also a certain accompanying disadvantage. On the one hand, it is not so easy as in freer lands for the unworthy to impose upon the credulity of the community; but on the other hand the censorship of the Government sometimes proves trying to those who are worthily pursuing their avocations. An illustration of this is to be seen just now in Austria, where the members of the medical profession are endeavoring to obtain from their Parliament modification of an existing law, which imposes a fine of one hundred florins (about fifty dollars) upon any practicing physician or midwife who, without a satisfactory reason, refuses assistance in any case where it is urgently needed and cannot be obtained from others. This law the physicians of Austria wish to have amended so that it shall name the diseases or conditions in which assistance shall be regarded as "urgently needed," so that the construction of the term shall not depend upon the fears or prejudices of the people. They also ask that a provision shall be inserted, that the Courts shall not consider any complaint under this law until after an opinion on the case has been obtained from a competent medical man.

Our sympathies go with our brothers beyond the sea in this matter, and we agree with them them that the law, as it now stands, contains a needless imputation against the fidelity of the profession; more than that, it furnishes altogether too easy a method for bringing a most serious and damaging accusation against any individual physician who may incur the ignorant or malicious ill-will of others. It is not so much the matter of the fine, but rather the shame of the thing which we find objectionable.

In this country we know of no law on this subject; although we believe that a Court has held that a physician must respond to the call of those who summon him, unless he can give a good reson for refusing to do so. This, however, is no source of danger here; and a physician must be in bad plight who cannot justify his conduct in a case in which humanity does not demand his immediate response—and if one refuses when humanity demands his action, he ought to suffer for it.

For the present, for these and other reasons which we cannot now go into, we may be satisfied with the state of our own laws on the subject, and hope our Austrian colleagues may get rid of theirs.

—If you use a fountain pen, and find it difficult to unscrew the tip, wrap a rubber-band a few times around it, and this will give you a good grip. A string or dampened piece of paper will also help.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

ELECTRICITY IN FACIAL BLEMISHES. By Plym S. Hayes, A. M., M. D., Late Professor of Chemistry and Toxicology, Woman's Medical College, Chicago, etc. 12vo, pp. 128. Chicago: W. T. Keener, 1889. Price, $1.00.

This small book is devoted entirely to the subject of the use of electricity in the removal of facial disfigurements, such us superfluous hair, port-wine marks, moles, and similar blemishes. The method referred to is that known as electrolysis. As to be supposed, the operation for the removal of superfluous hairs receives the greatest attention, and the several steps of this delicate operation are intelligibly described. The volume may be looked upon, indeed, as a counterpart of what is to be found in recent dermatological textbooks; but it is more minute in the details, and therefore probably of greater value to those who have had no experience in the use of this method.

ORTHODONTIA, OR MALPOSITION OF THE HUMAN TEETH; ITS PREVENTION AND REMEDY. By S. H. Guilford, A. M., D. D. S., Ph. D., Professor of Operative and Prosthetic Dentistry in the Philadelphia Dental College, etc. 8vo, pp. 186. Philadelphia: Spangler & Davis, 1889. Price, $1.75.

This book has been written at the request of the National Association of Dental Faculties, in furtherance of its plan to secure the preparation of a series of text-books for use in American Dental Colleges. In the first part of the book, the author discusses the principles involved in the correction of irregularities in the position of human teeth; in the second part, the materials and methods employed in correcting the irregularities; while the third part is devoted to a description of the specific forms of irregularity and to their treatment.

Dr. Guilford asserts that scarcely any deformity of the mouth and teeth is beyond mechanical remedy, but he cautiously adds: "What is possible may not always be advisable." His language is clear and to the point. The chapters and also the minor subdivisions are arranged so that any one can tell without difficulty what each page is about. The illustrations, of which there are eighty in all, are excellent. The book is handsomely printed on good paper and in clear, large type, so that in all respects it can be cordially recommended to students and practitioners of dentistry.

ESSENTIALS OF PATHOLOGY AND MORBID ANATOMY. By C. E. Armand Semple, B. A., M. B. Cantab.; L. S. A., M. R. C. P. Lond.; Physician to the Bloomsbury Dispensary, etc. 8vo, pp. xvi, 160. With forty-six illustrations. Philadelphia: W. B. Saunders, 1889. Price $1.00.

This book gives a very good general review of pathology, including inflammation, tuberculosis, the degenerations, tumors, diseases of the blood, syphilis, hypertrophy, atrophy, the pathology of the urine, and animal and vegetable parasites. The last three subjects are rarely considered in so small a work as the present one, but they are, in the main, very well treated. The illustrations vary greatly in relative merit; those of tuberculosis and of the tubercle bacilli are excellent, while those illustrating the parasite of ring-worm and of favus are very poor. It would have been much better, also, to have given a picture of ringworm of the scalp, showing the spores invading the hairs, than of ringworm of the body; for the latter is much easier to recognize than the former.

Dr. Semple has succeeded in compiling a very useful little book. He has given the important parts of the subject briefly but clearly. The printing, however, is from old plates or with much-worn type.

Literary Notes.

—*Lippincott's Magazine* for November contains an interesting article on "The Question of Pure Water for Cities," by William C. Conant.

—It is announced that on January 1, 1890, *The Journal of Comparative Medicine and Surgery* will appear with a slightly changed title, and as *The Journal of Comparative Medicine and Veterinary Archives* will be issued *monthly* instead of quarterly as heretofore. *The Journal of Comparative Medicine* will continue to note all new matters in the rapidly advancing progress made in the study of the anatomy, physiology, pathology, and therapeutics of all animals; and the scientific writers who have aided in establishing the reputation of the Journal as a pioneer in publishing original researches in regard to our lower brethren, will continue to contribute to its pages. The *Veterinary Archives*, once a month, will place before its readers immediately a comp'ete record of all the important and interesting discoveries, news and advances in veterinary medicine.

The subscription price is raised to $3.00, payable in advance. Subscribers who have already paid in advance will receive the monthly until the date on which their subscription terminates. The Junior editor, Dr. Huidekoper, will assume the active management of the Editorial Department instead of Dr. W. A. Conklin, of New York.

Correspondence.

Accusation against a Physician.

To the Editor.

Sir: There has recently come before the courts of Lackawanna County, Pa., a case of much interest to the medical profession. Especially is it valuable to the younger practitioners, some of whom, unless this lesson is heeded, may, like the unfortunate doctor in question, awake some morning to find themselves famous in quite another way than did the immortal Byron. Dr. X., a young physician of this city, was called hurriedly, one day last March, to see Mrs. M., a reputable married woman, living near him. He found her in a hysteroid state, and by questioning discovered that she was suffering from prolapsus uteri—such, at least, was her diagnosis. He discovered also that for

many years she had been accustomed to have "fainting spells," during which, however, she retained consciousness. He made an engagement for another visit on the 30th of the month, when he saw her at her home. There were present in an adjoining room the woman's little daughter and a servant girl, aged about seventeen years. According to the patient's story, the doctor placed her in Sims position on her bed; but, instead of proceeding with the vaginal examination, deliberately commenced to loosen her dress at the bosom and took further unwarranted liberties with her person. She shrieked and leaped from the bed, brandished a chair and drove him from the house. To this she testified under oath, and two of her neighbors testified that her little girl came running for them, and that upon arriving at the house, they found the woman sitting in a chair and "feeling bad." The doctor testified that, after placing the patient in Sims position he put one hand over the uterus, intending to make a bi-manual examination, and introduced his index finger into the vagina; that when his finger was partially introduced the woman leaped from the bed, began crying, and said: "I've been in my father's mansion for twenty years, and now I'm ruined." He endeavored to quiet her, but, not succeeding, left the house. Having previously made arrangements to leave the city—a fact not questioned by the prosecution—he did go, and on his return was arrested on the charge of attempt to rape with assault.

Testimony from several clergymen and other reputable citizens was introduced, showing the previous good character of the physician, also medical evidence to the effect that the plaintiff was hysterical and that vaginal examinations in this class of cases were often made the basis of unfounded and baseless charges against the physicians. One physician testified that he had been thus accused by an hysterical women, even though the examination was made in the presence of her own husband. Judge Connelly, in his charge to the jury, remarked that he was "firmly convinced that hysterical women under the excitement of a vaginal or uterus examination often made unfounded and unreasonable charges against their physicians." He further told the jury that, if a "reasonable doubt" existed in their minds as to the defendant's guilt, they should promptly acquit him. The jury was out nearly four hours, and returned with a verdict of *guilty*, though recommending the doctor to the mercy of the court.

Yours truly,

Scranton, Pa., S. M. W.,
Oct. 30, 1889.

Telephone Probe.

To the Editor.

Sir: In regard to the criticism on my probe in the Reporter, of Oct. 19, I beg to state, in addition to your reply—which was correct—that the "making" and "breaking" of a telephone circuit does not cause audible sounds in the telephone unless the points of contact be *metallic;* and that, although the current is partially closed, the moment the probe comes in contact with moist tissue, no indication is given until a metallic contact is "made" or "broken." I may also add that my invention does not only exist "on paper," but is a practical one, and will "act as described."

Yours truly,

Harvey B. Bashore, M. D.,
West Fairview, Pa.,
Oct. 26, 1889.

Notes and Comments.

Devouring Offspring.

Dr. William Duncan, in a recently published paper on the fer-de-lance, one of the *Crotalidæ*, or pit vipers, of the West Indian Islands, says that the female fer-de-lance devours her young in very wholesale fashion. This dangerous serpent is very prolific, and sometimes brings forth as many as two hundred young at a birth, seldom less than one hundred. Dr. Duncan says the female fer-de-lance, when about to bring forth her young, generally selects a fairly open or cleared space, a mountain footpath being a favorite spot. Along this she crawls slowly, dropping her young one by one on the way. As soon as the last has been brought forth, the faint and hungry mother turns and devours the first of her brood that meets her sight, and continues this unnatural course until satiated with her repast, or she finds no more of her offspring to glut her rapacity. Naturally many of them, three-fourths at least, escape, and these the strongest—a clear case of the survival of the fittest. This has been observed by several planters in St. Lucia, and has been mentioned to

me independently by Mr. E. S. Gordon, Mr. A. R. Marucheau, and Mr. Marius Devaux, and others of the colony.

These statements, taken from *Science*, Oct. 18, 1889, are directly contrary to observations made upon the crotalidæ of Asia, by Dr. de Lano Eastlake, who read a paper on this subject before the Japan Branch of the Royal Asiatic Society in 1886. Dr. Eastlake says that the majority of the crotalidæ bring forth only from ten to fifteen young at a time, and the fer-de-lance is no exception to this rule. Regarding the infanticide tendencies of the reptile, there must also be some mistake. The *mamushi* (*Triginocephalus Bloomhofii*) of Japan and China will frequently defend their young at the cost of their own lives, and the Japanese say that the infant vipers will run into their mother's mouth to escape from danger.

Extraordinary Abdominal Injury.

Mr. A. H. S. Todd, House-Surgeon, Monkstown Hospital, reports in the *British Med. Journal*, Oct. 5, 1889, an extraordinary abdominal injury, which occurred a few miles outside Dublin, during the haymaking season last summer. A man, aged 22, was working at a hayrick, and, for descent, slid down the side of the rick. Making an effort to clear the back of the rick, he alighted on the handle of a pitchfork which was stuck upright into the ground about two feet from the base of the rick. The handle entered his perineum, lacerating it to its full extent. With an effort he got off the pitchfork and walked round to the other side of the rick, when he fell down in a collapsed condition. He was then conveyed to Dr. Steevens's Hospital, where he was attended to by Dr. Myles, who washed out the wound in the perineum and found the sphincter ani completely lacerated and the lower end of the rectum "in a pulp," as he expressed it, the feces escaping involuntarily with clots of blood. He could discover no laceration into the abdominal cavity. On examination over the abdomen a peculiar splashing sound was elicited in the right iliac fossa, and the abdominal muscles were found board-like in their rigidity. At 6 P. M. Dr. McCausland and Mr. Todd made a further examination, and found urine escaping from the bladder mixed with blood. A known quantity of corrosive sublimate solution was injected into the bladder, which returned immediately in its entirety, negativing any communication with the perineal wound. The patient every five or ten minutes passed urine intimately mixed with blood; there was no ecchymosis in the loins, no pain felt down the ureters, and no anæsthesia in the upper part of either thigh. The patient rallied somewhat from the shock under the influence of opium, but died at 4 A. M. next morning. On *post-mortem* examination the abdomen was found enormously and uniformly distended with gas, and decomposition had already set in. Although the examination was made within twenty-four hours of death, *rigor mortis* was well marked. The perineum was lacerated from the central point to the coccyx. On incision an enormous quantity of gas escaped, the omentum and small intestines were found covered with a thick layer of feces, and a considerable amount of fluid was found in the pelvis (probably introduced in washing out the perineal wound). The small intestines were bruised and congested in several places; all the organs were congested; and, scattered here and there over the visceral peritoneum of the intestines, were little spots of adherent lymph, as though a certain amount of reaction had taken place before death. On examination of the kidneys, the left was found lying in a huge clot of blood in a lacerated and bruised condition. The rectum was lacerated in a longitudinal direction to the extent of two inches in its first stage, close to the brim of the true pelvis on its left side. The ureter, bladder, and prostate were uninjured.

Philadelphia Polyclinic.

The Philadelphia Polyclinic has recently elected the following Emeritus Professors: Dr. Richard T. Levis, of Surgery; Dr. S. Solis-Cohen, of Diseases of the Throat; Dr. Charles H. Burnett, of Diseases of the Ear; Dr. Charles B. Nancrede, of General and Orthopedic Surgery.

An additional chair of Orthopedic Surgery was established, and Dr. Thomas G. Morton was elected to it.

A department of Dentistry was created. A department of Experimental Therapeutics and Physiology was created, and Thomas J. Mays, M. D., was elected Professor. The Clinical Chair of Surgery was filled by the election of Thomas S. K. Morton, M. D. Professor.

C. L. Bower, M. D., was elected Adjunct Professor of Clinical and Operative Surgery and J. Abbott Cantrell, M. D., Adjunct Professor of Diseases of the Skin.

The Chair of Pathology was left vacant.

Treatment of Endometritis.

In the treatment of the milder cases of endometritis, Terrier introduces medicated pencils into the cavity of the uterus. He recommends for this purpose, in the *Semaine médicale*, iodoform or corrosive sublimate:

℞ Iodoformi . . . . . gr. cl
Gummi tragacanth . . . . . gr. viiss
Glycerini,
Aquæ destil. āā . . . . . q. s.
Ut fiant bacilla (pencils) No. X.

The pencils made according to this formula are said to be about the size of sticks of nitrate of silver. Resorcin or salol may be used instead of iodoform.

Terrier recommends the following formula for making corrosive sublimate pencils:

℞ Hydrarg. chlor. cor. . . . . gr. viiss
Talc. . . . . ʒviss
Gummi tragacanth . . . . . gr. xxiij
Aquæ destil.,
Glycerini āā . . . . . q. s.
Ut fiant bacilli No. L.

The vagina is first washed out with a one per thousand solution of corrosive sublimate, and then the pencils are introduced into the cavity of the uterus. They are prevented from slipping out by tamponing the vagina with iodoform gauze.—*Wiener med. Presse*, June 9, 1889.

Treatment of Fractures of the Spine.

The treatment of fractures of the vertebral column entailing compression or of damage to the spinal cord, has not hitherto been either active or successful. The surgeon for the most part gives Nature a free hand, and beyond some attempt at fixation, does nothing except minister to each symptom as it arises. Of course there are cases in which the injury to the cord is so severe, that even under the most favorable circumstances the patient cannot hope to be spared the immediate paralysis and subsequent degeneration. There must, however, be others in which, as in corresponding injuries to the cranium, the damage is confined to pressure and irritation either from splinters of bone or laceration of the membranes, with hemorrhage. In this latter class of cases it seems possible that the surgeon may yet intervene with some prospect of success in relieving a condition which, if left to itself, soon brings about chronic nerve changes, resulting in permanent disablement and even a fatal result at no distant period. Mr. Herbert Allingham recently trephined in two cases of fracture of the spinal column, and although the improvement was not all that one could have wished, he at any rate succeeded in demonstrating, on the lines laid down by Mr. Victor Horsley, that the operation of exposing the cord is neither difficult nor dangerous. That, after all, is of more importance than the result in the first two or three cases, since his success, in so far as the operation itself is concerned, may tempt other surgeons to follow up the idea. It may almost be laid down as a rule in surgery in cases of injury to the spine, that if, at the end of a week, no marked improvement has taken place, the proper course is to explore.—*Medical Press and Circular*, April 24, 1889.

Polyclinic Therapeutical Society.

At the last meeting of the Polyclinic Medical Society, a therapeutical section was formed from among the faculty, clinical assistants, and students of the Philadelphia Polyclinic, whose object is the scientific and systematic investigation of the action of drugs and remedies in the cure of disease. The Executive Committee of this section formulates a programme of practical work for each meeting, decides what drugs or remedies are to be investigated during the following months, devises specific directions in regard to such investigations, and supplies printed blank forms to carry the work into practical effect, with which any member of the profession who desires to take part in the research will be furnished free on application. These blank forms are filled out by the observer and returned as soon as the investigation is completed, which will be at the end of one or two, and not later than three months; at which time the reports will be analyzed and presented at the following meeting with due credit to each contributor, and the results will be published in the medical journals. It is believed that a com-

bined effort on such a large scale will not only benefit those engaged in the work, but will be of great value to practical therapeutics.

Dr. Mays read a paper on *Olive Oil in Gall-Stones*, and olive oil in this affection was made a subject for investigation during the next two months. All communications in reference to this subject should be addressed to Therapeutical Section, Philadelphia Polyclinic.

Morphine and Morphine Solutions.

The *Pharmaceutical Journal and Transactions*, says M. Lamal, attributes the turbidity, yellow color, and acid reaction which are developed in aqueous solutions of morphine salts, as well as the separation of crystals, to the action of light and organized ferments (*Journal de Pharmacie et de Chemie*, January 15, page 62). The yellow color he considers to be due to the formation of an amorphous substance that appears to be identical with the morphetine of M. Marchand; the crystals are said to be the result of the oxidation of morphine to oxymorphine, and the acid reaction is referred to both morphetine and salts of oxymorphine. The formation of apomorphine in solutions of salts of morphine is denied. M. Lamal states, as the result of his experience, that an aqueous solution made with a perfectly pure salt of morphine and double-distilled water will remain unaltered as long as it is kept sheltered from light and atmospheric dust. In the organism, M. Lamal says, morphine is sometimes entirely, sometimes partially converted into oxymorphine, both the oxymorphine and any unaltered morphine being eliminated with the urine. It would be important, therefore, in toxicological investigations to search in the blood, urine, and vascular organs for oxymorphine, the presence of which would be an additional proof of the ingestion of morphine. —*National Druggist*, July 1, 1889.

Dextrin Mucilage for Embedding.

For those who use the freezing microtome, it will be found useful, in the present high price of gum-arabic, to know that gum-dextrin answers just as well as the former, and costs only about one-fifteenth as much. Mr. T. L. Webb writes upon this point to the *Provincial Medical Journal*, as follows:—"I find that by making an aqueous solution of carbolic acid (about 1 part of the acid to 40 parts of water) and dissolving therein sufficient dextrin to make a thick syrup, a medium is obtained which is superior to the time-honored gum and sugar in three ways. It freezes so as to give a firm support without becoming too hard; it keeps better than gum, in which several kinds of fungi are apt to grow; and it is much cheaper, costing only about fourpence (8 cents) per pound, while powdered gum accacia costs five shillings ($1.25). Dextrin dissolves but slowly in cold water, so that a gentle heat is advisable when making the mucilage."—*St. Louis M. and S. J.*, Oct., '89.

Beer Compared With Other Alcoholics.

For some years a decided inclination has been apparent all over the country to give up the use of whiskey and other strong alcoholics, using as a substitute beer and other compounds. This is evidently founded on the idea that beer is not harmful, and contains a large amount of nutriment; also that bitters may have some medical quality which will neutralize the alcohol which it conceals, etc. These theories are without confirmation in the observation of physicians. The use of beer is found to produce a species of degeneration of all the organs. Profound and deceptive fatty deposits, diminished circulation, conditions of congestion, and perversion of functional activities, local inflammations of both liver and kidneys are constantly present. Intellectually a stupor amounting to almost paralysis arrests the reason, changing all the higher faculties into a mere animalism, sensual, selfish, sluggish, varied only with paroxysms of anger that are senseless and brutal. In appearance, the beer-drinker may be the picture of health, but in reality he is most incapable of resisting disease. A slight injury, a severe cold, or a shock to the body or mind, will commonly prove acute disease, ending fatally. Compared with inebriates who use different kinds of alcohol, he is more incurable, and more generally diseased. The constant use of beer every day gives the system no recuperation, but steadily lowers the vital forces.

Recourse to beer as a substitute for other forms of alcohol merely increases the danger and fatality.—*Scientific American.*

NEWS.

—Five Chinese lepers were shipped home from San Francisco, Oct. 29, on a Hong Kong steamer. Among them was a man who was sent to San Francisco from New York, where he had been employed as a cook for laborers on the Croton aqueduct work.

—Dr. Isaac E. Taylor, founder of Bellevue Hospital Medical College, died suddenly, Oct. 30, in New York City, of pericarditis, in the seventy-eighth year of his age. He was born in Philadelphia in 1812 and was graduated at the University of Pennsylvania in 1834.

—The Indiana State Board of Agriculture has advices from many of the northern and northwestern counties saying that hog cholera is epidemic, and that hundreds of hogs are dying daily, and that the disease is steadily increasing. No remedies appear to have any effect, and all attempts to stop the spread of the disease have failed.

—The spread of diphtheria and scarlet fever in Lawrence, Massachusetts, has become so alarming that in all the Catholic churches Oct. 27 the priests warned the people not to visit from house to house any more than was necessary. It is stated that no funeral of the victims of these diseases will be allowed from the churches.

—Rear-Admiral J. H. Gillis writes from Montevideo, September 11, 1889, that yellow fever is breaking out in various parts of Brazil, also in the city of Rio de Janeiro. This indicates an unusually sickly season, and he strongly urges, that unless circumstances arise rendering the presence of one of our vessels imperatively necessary, none be permitted to visit infected ports of Brazil this year.

—At the last meeting of the Prussian Academy of Sciences, a large number of grants were made for scientific and medical purposes, amounting in all to 18,000 marks, or about $5,000. To Professor Brieger a grant of 1,800 marks ($500) was made to enable him to continue his investigations regarding the ptomaines, and to Dr. Fleischmann, of Erlangen, a like sum to enable him to procure material for his embryological researches. Many other grants were also made but were for biological or other scientific purposes.

—At a meeting of the Philadelphia Pathological Society held October 10, Dr. Henry F. Formad was elected President for the ensuing year, and Drs. John H. Musser, John Guiteras, H. R. Wharton, and A. V. Meigs Vice-Presidents. The retiring President, Dr. F. P. Henry, read his annual address, calling attention to the flourishing condition of the Society, and the valuable work which has been accomplished during the past year—work that will constitute a record of great credit in the coming volume of the Transactions.

—A remarkable occurrence is reported from Belgium, where several inmates of a newly-constructed almshouse died very suddenly and without apparent cause. Investigation revealed the fact that the water supplied to the institution, which came from a spring near by, contained 0.7 of a grain of arsenic acid to the gallon, and it has since been used medicinally as a substitute for Fowler's Solution. Arsenical mineral waters have been known before, but this is the first instance on record where fatal accidents have occurred from their use.—*Popular Science News*, Oct., 1889.

—Dr. C. A. Lindsley, Secretary of the Connecticut Board of Health, has nearly finished an examination into the causes of the prevalence of typhoid fever at Yale College. Of the eight cases among the 1,500 students at the college, of which three have resulted fatally, Dr. Lindsley finds that all began during the first two or three weeks after the opening of the college term, and that during the last two weeks no new cases have developed. Most of the cases came on almost immediately after the term began. Dr. Lindsley therefore is convinced that the seeds of the fever existed in all the cases of the affected students before they came to New Haven.

—The United States Consul at Tien Tsin, China, has notified the Department of State of an important step taken by Li Hung Chang, Grand Secretary of State for China. Li Hung Chang has decided to establish a medical service for the Chinese army and navy on the basis of the best Western models. That he may have the best of these to study, he has solicited the help of the State Department of Washington to obtain a complete collection of the present regulations of the Medical Department of our army and navy. The proposed Chinese service is to be under a foreign Surgeon-General with an adequate staff of assistants. It will include hospitals and dispensaries at various places, a medical school, and native surgeons for the fleet and the military stations of North China.

WHOLE No. 1707.] NOVEMBER 16, 1889. [VOL. LXI, No. 20.

NEW EDITION. JUST OUT.

REMINGTON'S PHARMACY.
(Second Edition.)
A Treatise on the Modes of Making and Dispensing Preparations, with Descriptions of their Properties, Uses, and Doses,
BY JOSEPH P. REMINGTON, PH. M., F. C. S.
Thoroughly Revised. Containing over 1300 pages and 630 illustrations, a net increase of over 200 pages, with 140 illustrations.
8vo. Cloth, extra, $6.00. Sheep, $6.50.

LEIDY'S ELEMENTARY TREATISE ON HUMAN ANATOMY.
New (Second) Edition, Rewritten and Enlarged. Containing 495 Illustrations.
By JOSEPH LEIDY, M. D., Professor of Anatomy in the University of Pennsylvania, etc.
8vo. Extra Cloth, $6.00. Sheep, $6.50.
"Its excellency is such as to leave no place in our mind for anything but praise."—THERAPEUTIC GAZETTE, Detroit, Mich.

THE STANDARD COMMENTARY FOR MORE THAN HALF A CENTURY.
UNITED STATES DISPENSATORY.
New Sixteenth Edition. Illustrated. Carefully Revised and Rewritten by
H. C. Wood, M.D., LL.D., Joseph P. Remington, Ph.M., F.C.S., Sam'l P. Sadtler, Ph.D., F.C.S.
Containing over 800 pages new material.
Cloth, extra, $7.00; best Leather, raised bands, $8.00.
Half-Russia, raised bands, $9.00.
For facility of reference, Dennison's Patent Index will be inserted for $1.00 additional to these prices.
The new edition is for sale by all booksellers, or may be had direct of the publishers, free of expense of transportation, by remitting the price.

J. B. LIPPINCOTT COMPANY, Publishers, 715 & 717 Market St., Philadelphia.

EVERY PHYSICIAN

prescribing Cod Liver Oil (and who does not?) wants to know that his patients get the best that can be obtained. This is effectually secured by specifying **" BAKER'S "** whose firm (established in 1830) have given the greatest attention to the improvement and perfection of this all important remedy. In the various conditions in which Oleum Morrhuæ is indicated the Practitioner must decide the best form of administration. To meet such conditions we offer:

BAKER'S COD LIVER OIL.

BAKER'S EMULSION WITH HYPOPHOSPHITES OF LIME AND SODA.

Baker's C. L. Oil with Ext. of Malt.

Baker's C. L. Oil, Lime and Wild Cherry.

Above goods are accessible through the wholesale trade to all Retailers, and may be prescribed with the utmost confidence as to Purity and Excellence.

JOHN C. BAKER & CO., PHILADELPHIA, PA.

Physicians and Students of Medicine

are invited to attend the meeting of the

THERAPEUTICAL SECTION

OF THE

POLYCLINIC MEDICAL SOCIETY

AND THE

Lectures on Practical Subjects

by members of the Faculty, delivered under the auspices of the Society,

——On Tuesday Evenings——

throughout the Winter Course, at the College Building,

N. W. Cor. Broad and Lombard Sts.

For announcement of full course of instruction, for physicians only, apply to

L. W. STEINBACH, Secretary.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe, and healthful Home.

Resident Medical Officers:

J. WILLOUGHBY PHILLIPS, M.D., S. A. MERCER GIVEN, M.D

Clinical Lectures.

MULTIPLE NEURITIS.[1]

BY CHARLES G. STOCKTON, M. D.,
BUFFALO, N. Y.
PROFESSOR OF PRINCIPLES AND PRACTICE OF MEDICINE, UNIVERSITY OF BUFFALO.

Gentlemen: I have the pleasure of showing you this morning a case which is, in a number of ways, worthy of our closest attention.

The history is as follows:—"Mrs. C., aged 41, born in England; has three children; menstruation regular until about a year ago, when it became irregular and the patient experienced numb feelings in the legs, feet, arms and hands; the feet felt puffed up, but were not so; pains in the legs, not constant, complained of; there is no history of syphilis; the patient had rheumatism eleven years ago, but the attack was not acute. She enters with a brownish complexion, and has a large mobile tumor in the right abdomen which reaches from the umbilicus, the spine, the left hypochondriac and the epigastric regions, down to the crest of the ilium. It never has been painful. Her sclerotics are slightly jaundiced and pigmented. She has a goitre dating back as far as her memory reaches. The tumor is hard, smooth, and regular in outline. Her temperature was 100.4° on entering; her appetite is fair, her bowels are regular, and her urine presents no peculiarity.

This woman came here because of lack of power in the hands and feet; but as I looked her over, to note the general appearance, the first thing that struck me was the complexion. Her eyes and hair are dark, the complexion dark brown but apparently not that which comes from nature, but one changed probably by disease. You notice in the neck an enlargement which has, very properly, been called a goitre.

[1] Delivered at the Buffalo General Hospital.

On asking the patient to hold up the hand, there is a little tremor, but it is comparatively steady. Her grasp with either hand is no stronger than that of a child of two years. There is not much atrophy of the hands, though they are not quite so well developed as they should be. On the thenar eminences of both hands, we see signs of atrophy, and between the thumb and forefinger, on the back, there is a well-marked depression. We see the same pigmentation of the hands as of the face and, in fact, all the rest of the body.

Let us now look at the feet and legs. Straightening out the legs, she says, gives her a cramp in the thigh. The position of the feet and legs is rather unusual; the great toes are turned inward by the internal group of muscles, there being a loss of power in the muscles of the peroneal group. There also seems to be less power in the extensors of the leg than in the flexors. She cannot bend the toes and foot upward—there is not the power of dorsal flexion. With my thumb and finger I can hold her foot, against her efforts to bend the knee. There is a little more power on the right side than on the left. She has no power at all to turn the foot outward. Evidently we have a paralysis of motion here: not complete, but nearly so at the periphery while the power increases as we go toward the trunk. Now let us see about the paralysis of sensation. On testing this by pricking with a pin, I find no loss of sensitiveness in the skin at present, but in the past I have found areas of diminished, but not entirely abolished, sensation.

We may also have paralysis of the nerve, presiding over nutrition—the trophic nerves. But in this patient outside of a small amount of muscular atrophy, nutrition is being well carried on.

It would be well, at this point, to see whether the reflexes are natural. You recollect that the tendon reflex at the knee should, with rare exceptions, be present in health. Here, we do not see the limb respond to the ordinary test, and I have never been able to develop any response at all to percussion applied in the proper manner.

Now let us see what kind of a gait the patient has. Is it a gait characteristic of ataxia, or of some other affection? You notice that this patient steps over the toes, as it were. The toe drops to the floor and she is unable to raise it, and she therefore has to lift her foot high enough to raise it over the toe. In fact, she has what might be called the drop-foot, similar to the drop-wrist observed in cases of lead poisoning. This is a very characteristic gait and very different from that of locomotor ataxia, in which it will be remembered, the patient has a peculiar staggering shuffle, striking forward with the heel first, the toe being raised; then the heel comes down and the toe drops. This patient has, so far as we can make out, a paralysis involving the nerves of the legs and feet as well as of the arms and hands, and possibly also of other parts of the body. This paralysis is disseminated through all four extremities, and is therefore a multiple one. All the symptoms taken into consideration the case is clearly not one of locomotor ataxia. The patient has never had any trouble with the sphincters and gives no history of girdle-pains which belong to locomotor ataxia, nor of lightning pains in any part of the body. She has, I believe, multiple neuritis; a form of disease recognized not long ago, and one which has formerly been mistaken for locomotor ataxia, and for this reason I have dwelled at length on the difference between the two diseases. It is a form of paralysis which is often alcoholic in origin and in the case in question there is a history of alcoholic habit dating many years back, and she says that when she discontinued the use of alcohol for any length of time her condition became improved.

In multiple neuritis there is pain in the part inflamed, which is sometimes exquisite but more often not very severe. There is also a greater continuance of the suffering than in locomotor ataxia. Pressure over the nerves increases the pain.

Neuritis is not an uncommon affection. A typical case, like this, is rare, but minor degrees are often met with. Persons who have numbness of one finger during the menopause are affected with a form of neuritis. Neuritis may affect a single nerve or may be found in both arms but the body in general is not affected, as is the case in lead poisoning. This case is plainly one of those which Lancereaux described some years ago as "alcoholic paralysis."

As far as the neuritis is concerned, I have no doubt but that the patient will get better, and have fair return of power to the hands and feet. When first admitted to the hospital she had a certain hesitancy in her speech and a very peculiar impediment, such as I have never heard before. This symptom is now much improved and her intellec-

tual improvement is also marked. When she came here she could not collect her thoughts without difficulty; she is now as bright as any one. The power of her hands and feet has also somewhat returned. This indicates that regeneration is going on in the nerve-filaments which were degenerated.

In the course of treatment, the first thing to do is to keep the patient away from alcohol, otherwise the disease will continue throughout life. The second indication is to keep such patients warm, for they often suffer from cold extremities. It is also found very useful to bathe parts that are paralyzed in tepid water and to rub them. We are now giving this patient salt and water baths. Another important point in the treatment is the use of electricity—the Faradic current when that will cause response, and, if this is ineffectual, the interrupted galvanic current. In this case the nerves have shown degenerative reactions.

Some authors recommend the use of strychnine, but for my own part, I think it is used too much in nervous diseases. Still I can see no objection to its use in this case. It is not so objectionable in diseases of the trunk and peripheries of nerves as it is in diseases of the cord. There can also be no objection here to the use of phosphorus in small doses and, while the long-continued use of arsenic would be impracticable, the latter drug might also be serviceable for a time. A good diet is necessary. The legs should be stimulated by massage and the patient should be encouraged to exercise her arms and legs as much as possible.

LEUKEMIA.[1]

BY JAMES TYSON, M. D.,

PROFESSOR OF CLINICAL MEDICINE; ONE OF THE PHYSICIANS TO THE PHILADELPHIA HOSPITAL.

Gentlemen: I bring before your notice, to-day, a case of extreme interest, the history of which I will develop in your presence and the diagnosis of which we will determine. The patient, J. A., from Lewistown, Mifflin county, Pa., a rigger by trade, began to ail in May, '88, but remained at work until Christmas, when he was compelled to stop all labor and has been unable to resume work since that time. His trouble began by the appearance, in the region of his spleen, of a dull, ill-defined pain. By throwing the weight of his hand on the spot, he was at first able to greatly relieve this troublesome symptom, but latterly his suffering could not be mitigated by pressure. This pain was accompanied by a good deal of headache, especially in the back of his head, by disorders of digestion, by constipation, by bleeding at the nose, by a falling away of flesh, and by increasing weakness, until he presents the clinical picture which we now see.

Let us supplement these voluntary statements of our patient by a more systematic inquiry into his symptoms and his present physical condition. He was always healthy until eight years ago, when he fell and sustained a fracture of the sacrum, from some effects of which he still suffers; these results seem principally to be a weakness in the back, associated with numbness, pain radiating down both legs in the region of the anterior crural nerves. Although this condition remained, he was able to resume his business; and apart from the history of this accident, he presents no record of further trouble. In fact his past has been remarkably free from sicknesses of all kinds. Then comes this story of a pain followed by emaciation; he tells us he has lost forty pounds since the first of the year. Percussion gives negative results in the upper thoracic regions, but running down in the left mammillary line, we very speedily reach dulness; this is possibly the heart, but we note that it extends into the axilla. This dulness runs down until it skirts the edge of the ilium; it extends some distance posteriorly, and reaches nearly to the median line in front, making a circular area of dulness, having about a diameter of eight inches with centre about midway between the crest of the ilium and the lower border of the ribs.

The splenic dulness ordinarily covers an area of about one and a half, or at the most, two inches square. There is nothing which could occupy this particular space except a tremendously enlarged spleen. The fact that the area of dulness does not vary with the position assumed precludes the possibility of its being caused by fluid. On the right side, in the nipple line, dulness begins a little above the point at which we expect it normally; usually we get liver-dulness in the sixth interspace or on the seventh rib. Here we have dulness at the sixth rib and in the fifth interspace; at the right mid-

[1] Delivered at the Hospital of University of Pennsylvania.

axillary line there is flatness, due to the liver, at the seventh rib, which is also a little higher than in health. The liver is therefore either slightly enlarged or possibly a little displaced.

With such symptoms, enlargement of the spleen, adynamia, emaciation and anæmia, an examination of the blood naturally suggests itself. This has been made in this case, with the discovery of a very large proportion of colorless corpuscles in comparison to the red cells; indeed as many as one colorless to five red; whence the diagnosis is easy. This man has leukemia—a morbid condition of the blood-making apparatus, resulting in the formation of an excess of colorless corpuscles, with the diminution, sooner or later, in the quantity of coloring matter of the blood. The term "leukemia," meaning literally white blood, simply expresses the most prominent symptom; it does not explain or define the disease. The diagnosis is therefore what is called a "symptomatic diagnosis;" it merely represents the symptom of the disease, not the trouble itself.

The blood-making apparatus includes the spleen, the lymphatic system and the marrow of bone. Splenic and lymphatic leukemia are of more frequent occurrence; probably one-half of these cases are splenic; next in frequency comes combined splenic and lymphatic troubles; then lymphatic alone, with myogenic leukemia, or that of the bone-marrow, last in the order of frequency. In this patient, there is no evidence of lymphatic involvement; in such cases there is not only an overgrowth in existing lymphatic cells, but there is as well, the formation of new lymphatic tissue. Nothing of this sort can be found here. The changes in the lymph glands are purely hypertrophic. In the spleen, the first change is an active hyperæmia in the part; there is no striking alteration in structure as yet; the spleen is simply darker, of softened constituence, with the lobules marked. Then changes in the Malphigian bodies become visible; measuring one to three lines in width, white, tough, true hypertrophies. The spleen pulp begins to atrophy as the Malphigian bodies enlarge.

When the pulp becomes more atrophied and more decided enlargement of lymphatic structure appears, the white of the Malphigian bodies contrasted with the pulp stained and with the coloring of the blood produces the effect called the "marbled spleen."

The proportion of white corpuscles to the red cell can vary to a great degree and yet be consistent with perfect health, changing from one in 250, to one in 400 red corpuscles. In leukemia, the ratio runs down to one in 50, one in 25, one in 3, and even one to one. Here there is one to 5. There is also in this condition a diminution in the coloring matter of the blood. This latter condition is recognized by the use of some such instrument as Fleischl's "Hemoglobinometer," which consists of a colored, wedge-shaped bar lying horizontally on a platform and moved to and fro by a milled head; over this colored bar is placed a cylinder divided into two parts; one side containing the diluted blood; the other distilled water. The milled head moves the bar along under the cylinder so that it is beneath the compartments containing the distilled water and blood; then using proper light, which is generally the yellow ray of a candle, the bar is rolled along until the water has exactly the same tint as the diluted blood. From a scale on the side the percentage of hemoglobin is read off. Gower's instrument is on the same principle; in it, tinted gelatine is used, kept in test-tubes; with this tube, a given quantity of blood is compared, diluting it until it assumes the tint of the gelatine; then from a scale on the side of the tube the percentage can be determined. Gower's test is not as accurate as Fleischl's for the gelatine is apt to change in color after a time, and besides the manner of applying the test is not as delicate as it is in Fleischl's apparatus. It is however simple.

For counting the actual number of corpuscles in a given volume of blood, we use the microscope together with a slide marked off into a certain number of squares. The slide made for this purpose by Zeiss, of Jena, consists of a cell of $\frac{1}{10}$ of a millimetre in depth and ruled with a great number of squares each of which is $\frac{1}{4000}$ of a square centimetre or $\frac{1}{400}$ of a sq. millimetre. The blood-corpuscles in the properly diluted blood are counted in a number of these squares and the average taken for a certain number of squares; then knowing the dilution, the size of the squares and the depth of the squares we can obtain the number of red cells in a cubic millimetre of blood, which in the healthy man should be about 5,000,000 corpuscles.

The calculation in this case has been made and it is found that there are but 1,337,500 of red cells in this man to the

cubic millimetre, which is sufficient to amply explain his appearance. The ratio of white corpuscles to the red has been determined to be one to five; also by Fleischl's apparatus the hemoglobin has fallen to 30 per cent. Thus we see that everything in the blood has suffered deterioration; the number of red corpuscles, the ratio of white to red corpuscles and the coloring matter.

As to the exact stage of the disease which this man has reached, we need not believe that the trouble has run yet to its extreme limits. The spleen has probably not reached the condition of the "marble spleen," although there doubtless is a great increase in the lymph-adenoid tissue. One quite remarkable feature of the case is that though living in a markedly malarial district, he has never had any evidence of trouble of that sort. This is interesting to note in a case of this kind.

As regards treatment, we have reason to believe from past experience that his case is inevitably fatal, sooner or later, and hence although we may be able to delay the progress of the disease, he will die ultimately from exhaustion. If such a case is seen earlier in its course, there is a greater probability of effecting a cure. At such a period too it is difficult to say whether it is leukemia rather than ordinary anæmia. There will be found at this stage, a diminution in the coloring matter of the blood but no change in the ratio between the red and white corpuscles. Hence the importance of recognizing and arresting the condition of anæmia whenever we meet it. There is not a wide range of treatment adaptable to these cases; we are limited to making rich blood and strengthening as far as we can the system from the ravages of the disease. Iron and arsenic are the principal stand-bys to be used; the effect of such drugs on these cases is that they cause ordinary anæmia generally to leap into good condition; this is especially the case when heavy doses of arsenic are given. Perhaps the best form of iron to give is the carbonate, and of arsenic, Fowler's solution. The latter drug exerts even in leukemia marked, although it rarely produces permanent results. With this should be combined proper food, bloody meat, blood-making articles. As a *dernier ressort* transfusion of blood may be tried; and it may serve to afford temporary relief.

Gnomium, the new metal announced by Drs. Kruss and Schmidt, of Munich, is said to be a myth.

COMMUNICATIONS.

EXTRA-UTERINE PREGNANCY.

BY CHARLES P. NOBLE, M. D.,

SURGEON-IN-CHIEF TO THE KENSINGTON HOSPITAL FOR WOMEN.

At the present time when the subject of extra-uterine pregnancy is still unsettled, every experience regarding this condition is of value, inasmuch as it may help to a solution of vexed problems. The questions which elicit most discussion in medical societies are: the primary site of the pregnancy, the probabilities of diagnosis before and after rupture of the gestative cyst, and the proper method or methods of treatment, during the early months. The case which I herewith report is of more than usual interest as bearing upon the present views concerning diagnosis:

Mrs. X., twenty-seven years old, has been married seven years. She has had one child, now five years old, and no miscarriages. Mrs. X. was a delicate girl of a neurotic type. Between the ages of eight and fifteen years she had four attacks of chorea. Menstruation was always painful, and accompanied with severe uterine cramps, and distressing headache. There was nothing of note about her labor or lying-in. Shortly afterward she began to have attacks of what was called "inflammation of the womb," "inflammation of the ovaries," "congestion," etc. During the past five years she has had twelve or fifteen such attacks—usually at her menstrual periods or after unusual exertion. These "spells" were characterized by cramps in each groin, so severe as to cause her to double up with pain. She was usually confined to bed three or four days, but never more than a week at a time. The attacks were never accompanied with marked fever. Mrs. X. has suffered from leucorrhœa since a child, but has never had an acute attack. Her bladder has always been irritable. Since the birth of her child dyspareunia has been constant and distressing. Menorrhagia and metrorrhagia have both been present. During these years Mrs. X. was usually under the care of a homœopath, and for a while was treated for laceration of the cervix by a female practitioner.

During the past summer Mrs. X. was in her usual health. Menstruation was regular until August, when the period was skipped.

Slight morning nausea followed, sufficient however to attract her attention. The breasts swelled, and became tender. She suspected pregnancy. September 2 she began to flow, and then concluded that the delayed period was brought about by "cold." The flow antedated the time for the second period by one week. After two or three days however the blood had a distinctly lochial odor. Owing to this and the fact that she passed "a mass" in the water closet, with some pain, she concluded that she had miscarried. This mass was not examined, as at the time it did not attract special attention, it being not unusual for her to pass clots at her periods. The pains in the hypogastrium became more marked and were accompanied by a feeling of faintness. The family physician was now called. In view of the history it was considered probable that miscarriage had occurred. An old laceration of the cervix was discovered, and also that a mass was present in the left side of the pelvis. Several fainting attacks now followed, preceded by severe pain, "different from anything before experienced." One day she fainted twice in the street. The flow at times was profuse, and then almost stopped. The odor remained lochial.

I was called in consultation to see Mrs. X. Sept. 17, when the preceding history was obtained. On examination it was found that the perineum and cervix were torn; the uterus was low, forward, and to the right side; to the left and behind the uterus a large hard mass was felt, blocking up the pelvis, and which was distinctly rounded, dome-shaped, and palpable from above; there was a small mass to the right, and tenderness was very marked. Upon questioning, the patient told me that she had suffered repeated attacks of rectal tenesmus, and also that she herself was aware that a "lump" was forming in her pelvis. No rectal examination was made.

The diagnosis of left tubal pregnancy following old bilateral tubo-ovarian inflammation was made, and it was thought highly probable that rupture into the left broad ligament had occurred. This diagnosis was given the family, and operation urged. Influenced by what has been said of late concerning the impossibility of knowing anything about this subject, I further stated that it might prove to be hemorrhage from old tubal disease, provoked by a miscarriage, but that this was highly improbable. The patient remained in bed and was seen on the 19th. In the meantime she had been comfortable. The mass was more easily palpable, the uterus lower and more to the right. Frequent and painful micturition was now very annoying. Operation was still more strongly urged.

On the night of the 21st a severe fainting attack showed the family the necessity for action, and Mrs. X. was removed to the Kensington Hospital for Women for operation. Prof. Kelly and Dr. Robb saw the patient immediately before the operation and confirmed the diagnosis. Abdominal section was performed in the presence of Drs. Kelly, Boyd, and Deekins, of Phila., and Dr. Burr, of Wilmington, with the skilful aid of Dr. Hunter Robb.

The peritoneum was found blood-stained, and when the peritoneal cavity was opened some fluid blood escaped. The omentum was loosely attached to the broad ligaments and uterus, and when the attachments were severed, blood, which had been walled in by the omentum and bowels, escaped in large quantities. Handful after handful of sausage-shaped clots were removed—their peculiar shape attracting attention. The total amount of blood in the cavity of the peritoneum was at least a quart. The ovary and tube on the left side were freed from adhesions and tied off. The ovary was of normal size but the tube was much enlarged and filled with blood-clot which was escaping from the fimbriated extremity. On the right side was found a small ovarian tumor, and a hydro-salpinx. These were also tied off and removed. The peritoneal cavity was now flushed with warm water, especial care being taken to wash up clots from the sac of the hæmatocele. A drainage-tube was inserted and the abdominal incision closed.

The after history has been uneventful. The tube was removed after thirty-six hours. The convalescence was afebrile and without an unpleasant incident.

Upon laying open the left tube (which was unruptured) an ovum, of about seven weeks' development, was found near the uterus. Hemorrhage had been caused by partial separation of the ovum from the tube. The pressure of the blood had dilated the tube and its abdominal orifice; and hemorrhage continuing the formed clots were forced out into the peritoneal cavity.

The diagnosis in this case was easy. Every point required for diagnosis was present, except an examination of the

decidua. The clinical history was that which has long been looked upon as diagnostic of this condition, and which can be obtained in so many cases if the practitioner will only look for it.

The fact that the blood was within the cavity of the peritoneum is of special interest, because it has been taught that when a hæmatocele is dome-shaped, smoothly rounded, and palpable above the brim of the pelvis, it is contained within the layers of the broad ligament. This rule is evidently not infallible.

ASPERGILLUS IN THE HUMAN EAR.[1]—WITH REPORT OF ELEVEN CASES.

BY CHARLES H. BURNETT, A. M., M. D.,

AURAL SURGEON TO THE PRESBYTERIAN HOSPITAL; ONE OF THE CONSULTING AURISTS TO THE PENNSYLVANIA INSTITUTION FOR THE DEAF AND DUMB; LECTURER ON OTOLOGY IN THE WOMAN'S MEDICAL COLLEGE, PHILADELPHIA.

In a paper on twenty cases of this form of aural disease already published elsewhere (see foot-note), the following synopsis was given:

The age varied from fifteen years to sixty-seven years; fourteen cases occurred in men and six in women; the right ear was affected in seven cases, the left in nine; and both ears were affected in four instances.

The symptoms of the growth of this parasitic fungus of the mould family, in the human external ear may be briefly given as stinging, itching, dulness of hearing, some pain, and a watery but scanty discharge. The patient may finally complain of great pain and deafness, if the membrana tympani should become inflamed. An ear thus affected will show, on examination, the presence in it of a grayish, sometimes mottled, flaky mass, or, if examined in the earlier stages of the disease, it reveals the presence of a white false membrane closely adapted to the membrana tympani and the inner part of the auditory canal. From this point the false membrane may, and sometimes does, extend outward until it projects from the orifice, at the concha of the auricle.

A microscopic examination of a piece of this false membrane will demonstrate the true nature of the foreign substance in the ear by revealing the characteristic mycelial web and fructiferous hyphens of the aspergillus.

There are two forms of aspergillus found in the ear of man, viz.: the *a. glaucus* and the *a. nigricans*, which are marked in the accompanying figure A and B respectively. The latter is by far the more common in its occurrence.

Case 21. Aspergillus nigricans in the left ear; then in the right ear. Treated by solution of Hyposulphite of Soda.—Miss W., age 17 years, consulted me Feb. 7, 1879, concerning her left ear. Her parents stated that for several years she had had attacks of soreness and pain in the left ear. The hearing was found to be nearly normal. The membrana tympani was found covered with a blackish layer. Some pus was found at the meatus. Syringing brought out from the ear a dark, purplish and black mass. Some flakes of the same kind were removed by forceps from the canal. The microscope revealed the presence of the *A. nigricans*, (Fig. B) in all stages of growth.

Treatment.—The patient was directed to instill into her ear, every hour, ten drops of a three-grain solution of the hyposulphite of soda. In three days, when the patient was next seen, another mass of aspergillus was found in the fundus of the ear. The ear had been painful and sore for forty-eight hours. The mouth of the canal was eczematous, swollen and sore to the touch. Besides ordinary aspergillus fruit-stalks, there were found at this time some very large purplish fructiferous heads, four times the usual size, apparently enveloped in a membranous sac, suggestive of the so-called ascomycete

[1] These eleven cases are additional to twenty cases published in the *American Journal of Otology*, April, 1879. Their numbering will, however, begin with No. 21.

form of the aspergillus. The drops of hyposulphite of soda were continued every hour. On the next day some more fungus was removed, showing that it was still alive and growing; but there had been no further pain in the ear. The next day the membrana tympani was entirely free of aspergillus but appeared macerated. The drops were used four times daily, the patient not syringing her ear.

The next day the membrana was clearer; a little eczema still prevailed on sides of canal and at the meatus. The drops were ordered to be used three times daily.

Four days later the patient was seen again and the ear was found entirely free of the fungus. There was a little discharge from the eczematous spots in the canal. The eczema was successfully combatted by using a powder of equal parts of Hubbucs oxide of zinc and starch. In four days more the left ear was entirely well and remained so. Just at this time the patient stated that her *right* ear felt stopped, and uncomfortable, and that a *watery* discharge had come from it upon her pillow. Syringing brought out a mass of what proved to be *aspergillus nigricans*. This ear was treated by instillations of the hyposulphite of soda, in solution as above, without syringing, twice daily for a week, when it was found free from fungus.

The important points in this case are, the treatment by solution of hyposulphite of soda, requiring ten days to cure the left ear, and a week to destroy the fungus in the right ear, a comparatively long time, and, the interesting fact that the fungus was transplanted from the left ear to the right, probably by the fingers of the patient in performing her toilet.

Case. 22. Aspergillus nigricans in the right ear. — On December 6, 1879, Mr. L., aged eighty-three years, in whose ear I had inserted a week previous a cotton pellet over a perforation in the membrana tympani, as an artificial membrane, complained of discomfort in and some discharge from the ear. The artificial membrane was removed and with it some suspicious flakes of membranous substance. These being examined microscopically revealed the presence of a flourishing *aspergillus nigricans*.

Treatment.—The ear was treated by instillations of absolute alcohol, once daily for two or three days, when the fungus disappeared from the ear, and the patient ceased to feel the peculiar discomfort in the ear which had been caused by the parasitic growth.

It should be observed that in this case it required six or eight applications of alcohol in the ear to insure the destruction of the aspergillus.

Case 23. Aspergillus nigricans in the right ear.—Dr. X., age eighty years, Aug. 31, 1881, complained of itching, slight pain in, and a thin, watery discharge from, his right ear. Examination revealed on the posterior wall of the auditory canal and over the membrana tympani, a flourishing false membrane. There was a small perforation in the posterior-inferior quadrant of the drum-membrane. The microscope revealed the presence of the fungus, *aspergillus nigricans*.

Treatment. — Pure alcohol was instilled into the ear, producing intense burning as the skin in the canal was broken and macerated by the eczematous condition always found where the fungus has begun to flourish. Syringing removed a large piece of false membrane.

The next day the walls of the canal and the membrana tympani were much clearer. There was no more itching in the ear and it felt more comfortable, though a little muffled. The pink mucous membrane of the drum-cavity could be seen through the perforation in the membrana. The patient was ordered for instillation at home,

℞ Alcohol . . . . . f℥i
Aquæ . . . . . f℥vii
M.

The next day more false membrane had formed and was removed. Patient ordered to go on with the alcohol and water instillation, twice daily. The next day no aspergillus was found and the alcohol instillations were discontinued.

Two days later aspergillus was found again in the ear and the alcohol instillations were renewed. Instillations of a three-grain solution of sulphite of soda were also used in the affected ear. The next day a thin false membrane was wiped out from the ear and powdered boric acid was blown into it. This made the ear feel comfortable and it was allowed to remain in the ear. The next day no aspergillus could be discovered; but the ear still discharged mucus and the walls of the auditory canal were macerated and red. Powdered boric acid was blown into the ear again a few times, after which the aspergillus did not again appear and the ear healed.

This case, like the preceding, required continual watchfulness and treatment for a week, with alcohol, and sulphite of soda instillations in order to destroy the fungus—a much longer and more tedious method than that of *salicylate of chinoline*, as will be shown in the accounts of some subsequent cases, in this paper.

Case 24. Aspergillus nigricans in the left ear.—Mrs. X. complained of a stopped feeling, and itching in her ear, with a slight watery discharge; Nov., 1881. Examination revealed the presence of a false membrane, looking like a piece of wet newspaper, over the membrana tympani. The false membrane was removed from her ear by syringing, and enough of a powder composed of

Resorcin	1 part
Boric acid	16 parts

was blown into the ear to cover the membrane and the walls of the canal about it. This one treatment seemed to sterilize the fundus so that there was no reproduction of the fungus, and with this case begins the treatment of aspergillus in the ear, by means of boric acid in combination with with resorcin or salicylate of chinoline, preferably the latter.

Case 25. Aspergillus glaucus in both ears.—Mrs. W., age 35 years, stated, Oct. 7, 1882, that her left ear had annoyed her for some weeks, by some pain, itching, dulness of hearing, and latterly by a watery discharge. She had put some oil in the ear for relief. Within a few days of her visit to me the other ear, the right, had shown the same symptoms. On examination both ears revealed the presence of a false membrane, pale gray in color, covering the membrana tympani and the inner end of the auditory canal, near the drum. The ears were syringed with alcohol and water and the false membrane thus removed. In order to sterilize the fundus of the auditory canal and the membrana tympani, a powder composed of

Salicylate of chinoline	1 part
Boric acid, ...	16 parts

was blown into the ears, in quantity sufficient to lightly cover the parts named. This one application destroyed the fungus germs in the left ear, no false membrane was formed, and the ear became entirely normal in three days. The above powder, being found dry in the left ear, was allowed to remain there for about a week, when it was washed out. The right ear required a second application of the powder, before it showed no regrowth of aspergillus at its fundus.

Case 26. Aspergillus nigricans in both ears.—In Sept., 1883, F. S., age twenty-five years, applied at the Philadelphia Polyclinic for relief from discomfort and hardness of hearing in both ears. A false membrane, looking like wet newspaper, was found in each ear at the fundus and over the membrana. Syringing the ear by means of alcohol and water removed the false membrane, after which the ears were insufflated with a powder, as in the previous case, composed of

Chinoline salicylate	1 part
Boric acid	16 parts

The one application destroyed the fungus, and the ears rapidly became normal.

Case 27. Aspergillus nigricans (?) *in the right ear.*—On October 31, 1883, Dr. K. consulted me on account of itching, tinnitus, and some pain in his right ear. Six months previous he had suffered from an attack of acute otitis media in this ear, attended with perforation of the membrana, great discharge and deafness, for which he was treated in another city.

Upon examination the right membrana tympani was found dotted over with white spots, with intervening pink surface of the drum membrane. The latter was distorted from the previous attack of otitis.

The fundus of the affected ear was then slightly dusted with the aforesaid chinoline, boric acid powder, one to sixteen, which arrested at once the growth of the aspergillus. The microscope revealed only a dense mycelial web, growing in one of the white spots observed in the drum, but without fructiferous hyphens; hence the variety of the aspergillus could not be determined.

When seen in a few days the tinnitus and discomfort in the ear had ceased, and there was no further evidence of life in the fungus. A little plain boric acid powder was then blown into the ear, to favor a continued sterilization of the fundus, and allowed to remain there a few days, when it was washed out, and the ear appeared entirely free from any evidence of the presence of aspergillus.

Case 28. Aspergillus nigricans in the lef

ear.—On July 25, 1885, Mrs. J. S., age thirty-five years, complained of itching, sense of fulness in the left ear and hardness of hearing, which she had felt for some weeks. The auditory canal was abraded, apparently by a pin used for scratching it. A large mass of false membrane was found in the fundus of the canal and syringed out with alcohol and water. The microscope revealed the characteristic hyphens and spores of the aspergillus nigricans.

Treatment.—One application of the powder, composed of

Chinoline	1 part
Boric acid	16 parts

sufficed to destroy the fungus and arrest its further growth in the ear.

Case 29. Aspergillus nigricans in the right ear.—Mrs. S., age 45, stated on Oct. 12, 1885, that for six weeks previous there had been itching and soreness in her right ear, soon followed by a watery discharge. This patient was under treatment for aspergillus in both ears in 1876, and again in the spring of 1885. Examination revealed at the time of the last attack, Oct. 12, 1885, a false membrane covering the membrana tympani, and the adjacent walls of the auditory canal.

Treatment.—This time a different and an entirely new treatment was pursued in this case. The ear was syringed with alcohol and water, which removed most of the mycelial mass from the ear, and then there was blown into the ear and down to the membrana and the fundus of the auditory canal, a little powder composed of

Chinoline salicylate	1 part
Boric acid	8 parts

This was left in the ear until the next day when, as it was damp with the discharges from the eczematous walls of the auditory canal, it was syringed from the ear by means of alcohol and water, and some of the same kind of powder blown into the ear.

This treatment was repeated a few times, when it was found that the ear was entirely free from fungus and was normal in every respect.

Case 30. Aspergillus nigricans in the right ear.—July 13, 1887, Mrs. C. M., age 60 years, stated that a week previous she had felt a throbbing in her ear which then soon became stopped up and dull of hearing. Two months before these symptoms she had suffered from an attack of acute purulent otitis media, with perforation of the membrana tympani, but from which she had entirely recovered.

Examination revealed the presence of a false membrane over the drum membrane, which was syringed out with alcohol and water. Some of the chinoline and boric acid powder, as given above (1 to 16) was then blown into the ear. The next day the powder was found to be dry in the fundus of the ear, there were no signs of reproduction of the fungus, and the ear felt entirely well. No further treatment was necessary, the *one* application of the chinoline and boric acid powder having destroyed the fungus and cured the ear.

Case 31. Aspergillus nigricans in the right ear.—September 24, 1889, Mr. M.S., age thirty-five years, stated that he had felt discomfort, with attacks of great pain at times, in his right ear, and that a watery, with finally a purulent and offensive discharge, had come from the ear, for a period extending over six months, the first attack having occurred in the previous March. The hearing had varied in this time from a dulness to a marked deafness. Examination revealed a partly detached false membrane at the fundus of the canal and over the membrana tympani. Most of this was syringed out with alcohol and water, the rest was removed with slender forceps. Microscopic examination of the false membrane revealed the presence of the A. nigricans in all stages of growth. The fundus of the ear was then insufflated with some of the chinoline-boric acid powder (1–8). This was allowed to stay in the ear twenty-four hours.

The next day the patient stated that his ear had felt perfectly comfortable and that his hearing was nearly normal for the first time in six months. During this long period of suffering he had been under treatment, at the hands of a physician who had diagnosticated the true nature of the disease, but who failed to relieve him, chiefly I think because he had used aqueous solutions, which, in my experience, tend to favor the growth and development of fungus rather than their destruction.

The next day the powder was found to be a little damp from the discharge from the eczematous skin in the fundus of the canal, which condition is always excited in the canal by the continual presence of the aspergillus.

This moist powder was therefore washed out, and some fresh chinoline boric acid-

powder blown in. The ear from this time required no further treatment, as it became and has remained, entirely normal.

In the foregoing eleven cases it is worthy of note that in all there were symptoms of slight pain, dulness of hearing, then a watery discharge, with a spontaneous detachment of some of the false membrane from the membrana.

The following synopsis is of interest:

Sex—Men, 5; women, 6.
Age—Varied from 14 years, a girl, to 83 years, a man.
Ear—Right, 6; left, 2; both ears, 3.
Variety—A. nigricans, 9; A. glaucus, 1; doubtful, 1.
Treatment—Hyposulphite of soda, 1
Alcohol, ... 1
Hyposulphite of soda and alcohol, 1
Powdered boric acid and resorcin, 1
Salicylate of chinoline and boric acid, ... 7

Women predominate in number because they are more apt to scratch and pick their ears with pins, etc., thus inviting the growth of the fungus on the denuded parts Of the cases affected in both ears, two were women.

The only case of *A. glaucus* was in one of these women, affected in both ears.

The majority of the eleven cases (seven in all) were treated with chinoline salicylate in combination with boric acid (1–8, and 1–16 parts) and it will be observed that these cases were cured very much more easily and rapidly than those treated by other methods. Case 31, shows that unless the fungus is killed, it will continue to grow in the ear, and annoy the patient for months. In time it may induce a serious myringitis, perforate the membrana tympani and take root in the tympanic cavity.

Therefore any treatment so convenient, painless, prompt and efficient in its results, as the insufflation of chinoline salicylate in combination with boric acid, into the affected ear, should command the attention of all practitioners of medicine.

An Irish Rabies Doctor.—McGovern, the Irish Pasteur, who treats hydrophobia on a system handed down through generations of his family, recently received £12 from the Newry Board of Guardians for successfully treating four patients the Board had sent him.

Reports of Clinics.

UNIVERSITY HOSPITAL.

SURGICAL CLINIC—DR. ASHHURST.

Hydrocele.

Dr. Ashhurst first showed a man with hydrocele, and of this disease he said that there are three varieties, viz.: Congenital, when the elevation of the scrotum causes the fluid to flow back into the abdominal cavity. If there is a concomitant hernia, a truss should be worn. The patient often recovers spontaneously. 2. Acquired, when it follows orchitis, an injury, or is without any assignable cause. 3. Encysted, when the fluid is not in the tunica vaginalis proper, but in a cyst on the testicle or epididymis. Its fluid is watery or milky and when it contains spermatozoa, the cyst is called a spermatocele. There is also a hydrocele of the spermatic cord, of which there are likewise several varieties.

The symptoms given were these: there is a swelling of the scrotum, pear-shaped in form, or, if it is very full, it may assume the shape of an hour-glass. Its increase in size is in the longitudinal direction, and this characteristic distinguishes it from a sarcocele, the greatest diameter of which is usually transverse. It begins from below, whereas a hernia begins from above and, while a hernia clings to the central axis of the body, the tendency of a hydrocele is to turn outward. It is translucent by transmitted light, except when its walls are very thick or its contents dark-colored. Moreover, solid tumors are sometimes translucent. The specific gravity of a hydrocele is less than that of a solid tumor except when the former is extremely tense. He said that the palliative operation, which consists in tapping the hydrocele, could be repeated if it returned. This plan of treatment was recommended in very young, in feeble or in aged persons. If the sac continued to refill, it might be treated by a more radical operation, of which there were several kinds: the best being the injection of a stimulant liquid into the tunica vaginalis, generally the tincture of iodine. This injection is to be performed after the fluid has been withdrawn.

The testicle is usually situated in the posterior and inferior part of the scrotum. In this case it was anterior. Dr. Ashhurst

said that it and the larger blood-vessels should be avoided in making the puncture; and this he now proceeded to do, drawing off about four ounces of an amber-colored liquid, followed by a little blood. The testicle was itself much enlarged. As the after treatment, a suspensory bandage and rest for two days were recommended.

Removal of an Epithelial Cancer of the Lip and Chin.

The next case was that of a man with an epithelioma, involving the lower lip and chin. On the lower part of the chin and slightly to the right of the median line the infiltration had proceeded so far that ulceration had already begun. The case was a serious one and this had been fully explained to the patient. An operation, if successful, would however relieve the patient at least for a time. The most favorable circumstances about the case were that the floor of the mouth had not yet become involved; that the patient was otherwise healthy, and that he was only fifty-four years old. Had he been seventy-four, no operative interference would have been justifiable. The patient had been already etherized and the operation, which was long and tedious, was now begun.

The lower lip was first removed, leaving a rectangular space; then from either corner of the mouth as well as from the lower angles of the wound, incisions were made outwardly, forming two flaps, involving the whole thickness of the cheek and about 3 inches long by 1½ inches broad. These flaps were joined in the median line in front to form the new lip. The ulcerated portion below the chin was next removed, and the floor of the wound thoroughly scraped. To the sound tissue, intervening between these two excisions, the two flaps that had been taken from the cheeks and united to each other in the median line in front, were secured above, and, below, flaps taken from the neck and slid upwards. The wounds were all accurately closed with hare-lip pins and shotted sutures.

—Dr. Dutze, formerly assistant in Dr. Unna's clinic at Hamburg, has been invited to proceed to Honolulu by the Hawaiian Government, and to remain there some time to study leprosy and to investigate the effect of new methods of treatment.

COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK.

VANDERBILT CLINIC.

MEDICAL CLINIC—PROF. F. DELAFIELD.

Cirrhosis of Liver, with Chronic Catarrh of Bile Ducts.

The first patient was a man 55 years old. This patient was presented to the class, Dec. 10, 1888, and the diagnosis of hypertrophic cirrhosis was then made. He gives the following history: One year and a half ago he complained of pain in the back, gastric symptoms, a "lump" in iliac region, stools white, urine deep red, skin jaundiced, and said that he had lost strength and flesh.

The record shows the patient was given ice water enemata without benefit, and then was put upon a course of the alkalies—also without benefit. To-day we find the man's general condition not improved; he is emaciated, but not very much so; his face is of a dusky brown color (as in all old cases of jaundice); the conjunctivæ and the skin are yellow; his urine is still bile-stained, and has a specific gravity of 1.020. Of late he has had no vomiting and there has been no ascites, though during the past week he has noticed his feet to be a little swollen. He has complained also of diarrhœa immediately after taking food. Examination shows both right and left lobes of the liver to be considerably increased in size both upwards and downwards, extending at one point four inches below the free border of the ribs. The liver feels hard to the touch, and the surface is irregular and finely nodular. This condition can mean only one thing, namely, hypertrophic cirrhosis. The spleen is not increased in size; hence it is not congested, and the blood must pass freely through the liver. The absence of vomiting shows that there is no congestion of the stomach. These signs point to no obliteration of the portal vein or its branches, and hence we see the reason this patient has done so well and yet has been sick such a long time. The jaundice that he suffers from might be due to one of three things, viz.: chronic catarrhal inflammation of bile ducts, calculi in the common duct (not impacted but admitting of the passage of some bile), or cancer of the duct. This last condition is not probable, however, considering the general condition of the patient. Either of the other

two conditions is possible, and though the chances are in favor of catarrh, we cannot positively say this condition exists.

Treatment.—Can we do anything more for this man than has already been done? Though his general health is not decreasing very much, yet he shows no improvement. The indication is clearly to affect the catarrh of the ducts (and duodenum probably) if it can be done. For this purpose Dr. Delafield would suggest systematic washing-out of the stomach, doing this at first daily. The other indication is to feed the man better; and the lavage of the stomach will help along this endeavor. He should take more solid food than he has been taking (he has been largely on milk diet), and every effort should be made to have him digest and assimilate what he does take.

This case is an example of how long jaundice may exist and a patient still remain in good condition. A patient in different walks of life has other resources that cannot be extended to this man. Such an one should try a change of climate—this is of benefit in all catarrhal affections. And there is one mineral water that might prove beneficial, namely: the Ems water, provided it it taken at the springs. It certainly has helped very many old cases of jaundice.

Tumor of Kidney.

The second case was that of a man 35 years old, who had also been presented to the class. On April 25, 1889, he came to the Clinic complaining of slight gastric disturbance, malaise, and a slight jaundice. He had a temperature of 100°. A tumor was discovered in the region of the gall bladder, and the diagnosis of dilatation of the gall bladder was made. Under treatment the man improved, and by May 1 his temperature was normal.

His record shows that on May 10 he had lost two pounds in weight, and was not feeling as well as before; June 13, he had gained four pounds, but was feeling weak and unable to work; September 1 he had lost fifteen pounds, and was again a little jaundiced, with stools light colored, appetite poor, a cough, and a temperature of 100°. The tumor, which seemed to have at first decreased in size, now appeared larger.

On September 7 a second tumor was discovered by the side of the first, nearer the median line; it seemed hard and immovable. By September 19 he had lost four pounds; September 30, he had gained some flesh; October 17, he had diarrhœa with bloody stools. He has been gaining in weight, has very little cough, his appetite is fair, and he feels quite well—able to do light work. There is no jaundice.

Examination shows resonance over the lungs and normal respiratory murmur. The heart's action is regular and a little rapid. A murmur is heard with the first sound at the base. Inspection of the abdomen reveals an increase in size, especially on the right side. About six inches from the median line, just below the free border of the ribs, can be felt the original swelling, still soft and fluctuating, and corresponding in size and feel to the gall bladder. To the left of this, and extending an inch to the left of the median line, is felt the second mass noted in the history. It is hard and smooth and much larger than the original mass. In respiration both move with the liver. On deep palpation this second mass is found to extend deep down into the abdominal cavity, and with one hand forced well down in the lumbar region[1] the tumor can be seized and moved (apparent to the entire class). And for the first time it is found that both masses are probably one tumor. With the hand behind, pushing the tumor well forward, its size is discovered to be much greater than was at first supposed—indeed, it fills almost the entire right side of the abdominal cavity, but as it lies so deeply this was not apparent before. What was at first taken for an enlarged gall bladder was probably the most projecting part of the growth. Dr. Delafield said this was not the first time he had been misled by this condition. He believes now that the growth springs from the right kidney, it presses upwards against the liver and gives the impression that it is attached to that organ. The second mass discovered was simply an increase in the growth. Though the diagnosis is not absolutely certain he strongly believes it to be an adenoma of the kidney.

These cases are rare. The tumor will often grow to enormous size and the patient's general condition not be much affected, as in this case. And there are no changes in the urine. The question is: Should an operation for removal be performed? In view of the mobility and continued growth he would consider an operation feasible and perhaps advisable.

---

[1] See Editorial on Palpation of the Kidneys, MED. AND SURG. REPORTER, April 6, 1889.

Aortic Stenosis—Myocarditis (?).

The third patient was a man 47 years old, of intemperate habits, who had had a chancre fourteen years ago, and five years ago an attack of rheumatism. Last March, while lifting a heavy weight, he suddenly lost his sight, felt faint, and fell unconscious. Unconsciousness lasted one minute. He entered the New York Hospital, where he had several such attacks. It was noted that they would be ushered in by pain in the precordial region, and sometimes by vomiting. During the attack there was paleness of face, rolling of the eyes, slight convulsive movements of the arms, loss of consciousness, loss of radial pulse, and the heart sounds became almost inaudible. Their duration was about one minute. The man suffered, too, from dyspnœa on exertion, and pains in the head. His pulse varied between 40 and 50 per minute, and during one week, while in bed, it was between 30 and 40.

The specific gravity of the urine was 1.020, and a trace of albumin was to be found. The Hospital record mentions that during March a pericardial friction-sound was heard. At present patient complains less of heart symptoms and more of headache. He has not had an attack for four weeks. He knows he is steadily losing strength and flesh.

Examination.—The pulse was slow, and full, and good; some increase of tension. The heart impulse was diffuse, and the organ increased in size. A loud systolic murmur, whose maximum intensity was at the base of the heart, was heard. (This may have been the friction-sound noted above.)

Diagnosis.—Dr. Delafield said: It is evident this patient is suffering from organic disease of the heart. Aortic stenosis with dilatation of the ventricles is certainly present, but is this the whole story? The sudden onset, the fainting attacks, the increased arterial tension and the slow, regular action of the heart do not make the usual history of this condition, for they may all be accounted for by the aortic stenosis and dilatation.

But there may be some other change in the heart, and this history would make us look for it, viz.: Chronic myocarditis, with or without chronic inflammatory changes in the coronary arteries; and it is very probable that these conditions are present in this patient. So that it is safe to say the patient has aortic stenosis and perhaps also a myocarditis.

Foreign Correspondence.

THE HEIDELBERG CONGRESS.

"Alt Heidelberg, du feine, du Stadt an Ehren reich,
Am Neckar und am Rheine, kein' And're kommt dir gleich."

The Congress of Physicians and Naturalists—The Exhibition—The Scientific Discussions.

The 162d Congress of Physicians and Naturalists, just held at Heidelberg, was unanimously pronounced a most successful affair. To be sure the famous old city, around which song and legend have woven a most charming wreath, was in itself sufficient fascination to gather within its romantic walls the disciples of Æsculapius from near and far. "Thirst and Science," the old motto of Heidelberg, could be seen at its best during the Congress. No matter how heated the debates, how bitter the opposition and fight of the naturalists during the day were, one could see the contestants in the evening most cordially united around the historical "tun" in the happy enjoyment of wine and good fellowship.

I beg now to invite you to a short promenade through the exhibition, attached to the Congress, and then ask your attention to some notable topics of discussion. The object of most interest and admiration in the exhibition was Edison's phonograph, presented by the great American electrician in person at the first day of the meeting. Edison was honored not only by being placed at the table of the President, but also by repeated acclamations on the part of the assembly and by the flattering address of the Grand Duke of Baden. I am pleased to add that, by this time, the phonograph has taken up specimens of the voices of all German celebrities, including Bismarck and the Imperial family. Wolz, of Bonn, exhibited for the first time his new Knallgas light, which, after many futile attempts, he succeeded in preparing from compressed oxygen and hydrogen by the aid of zirconia. This light possesses superior advantages, particularly for the lighting of railroad cars, which could readily carry two receptacles filled with the gases mentioned. Sartorius, of Göttingen, presented a scale which was pronounced to be the finest in the world in precision and minimal

registration of weight. The Berlin analine works showed specimens of "eikonogen," a new "developer" for photographical negatives. Eikonogen permits of the development of pictures after a minimal exposure; the negatives develop rapidly and assume a very desirable blue-black coloration. The precipitate of silver in negatives treated with eikonogen is sufficiently delicate for the delineation of the finest details. Eikonogen can be kept for a long time in an alkaline solution and is wholly non-poisonous. The samples of photographs obtained by the aid of eikonogen were marvels of beauty and precision. Dr. Rohrbeck, of Berlin, exhibited a new apparatus for disinfection and sterilization, which claims our special attention on account of its embodying two important principles: viz., absolute exclusion of air, and the prevention of an overheating of steam. His disinfector is calculated to avoid the generation of dry steam, which, as experience has proven, is a less reliable germicide than moist steam. Seibert, of Metzlar, showed an objective by the aid of which the internal structure of bacteria can be distinctly recognized. The bacilli of anthrax, for example, do not appear under Seibert's objective as mere rods, as usually, but present a beaded internal structure invested by an irregular and nearly cylindrical sheath. The beaded appearance referred to does not by any means represent spores. Of considerable interest is the watching of microbic propagation, well known as the process of "budding." The beads located in the middle separate to a greater distance from each other, and a line of light is seen to cross the rod obliquely; then comes an indentation and ultimately the division of the rod. This is the highest power ever developed by any microscope. Among the numerous other exhibits I would mention an immense platinum-boiler for the concentration of sulphuric acid, a melted bar of pure iridium, and sublimated osmic acid. From the many interesting papers read and discussions held I shall select some few which invite our special attention.

At the debate on tuberculosis in the Congress Prof. Virchow opened the discussion by saying that Koch's bacillus did not explain all problems connected with tuberculosis and that individual, hereditary and possibly also other, as yet unknown, factors, probably play a more significant *rôle* in this affection than is usually believed at present. The hereditary element, at least, is no longer to be underrated since the tubercle bacilli have been discovered in the genital organs of parents, the offsprings of whom were known to be consumptives. Dr. Sonnenschein, of Worms, called attention to the origin of constitutional diseases, and of consumption in particular, from milk. He believes that a great portion of infants and children, dying of tuberculosis, have been infected from the milk of diseased cows. It cannot be doubted that the affection of cows, which the Germans call *Perlsucht*, is a tubercular process, and that provided the udder itself is implicated, the milk from such cows is under certain circumstances capable of rendering man tuberculous. The fact that *Perlsucht* and consumption are identical affections ought to be published broadcast and the sale of milk from cows thus affected rigidly forbidden. It has besides been proven that the composition of cow's milk becomes deteriorated and the milk itself unfit for use if the animal is fed on certain waste products of factories (beet-sugar refineries and distilleries). Children taking such milk contract the most serious intestinal catarrhs, and perish in large numbers. It will therefore be the duty of the state authorities to rigidly superintend the feeding of so-called milk-cows, and that of physicians to enforce the use of milk in a state of sterilization and in sterilized vessels.

Prof. Victor Meyer, the successor of Bunsen, read a valuable paper on "Chemical Problems of the Present Time." The author alluded to the great progress in the science of chemistry, made by the labors of men like Bunsen, Hoffmann, Rekulé, Van't Hoff, Baeyer, and Wisclicenus. Demetrius Mendeljeff has the credit of having established a natural system of elements, and of having first pointed out that the properties of elements are functions of the atomic weight. His researches have led him to believe that the number of elements in existence is one hundred, although only seventy are yet known with certainty. He separates the elements into two groups, of seven elements each, and five groups of seventeen elements each. This makes ninety-nine elements in all, to which as the one-hundredths hydrogen is to be added. This divination of thirty elements, as yet undiscovered, resembles somewhat the predetermination of Neptune in our solar system. Mendeljeff's studies, particularly in regard to the corrected figures of atomic weight and their comparison with the so-called homologous orders, point with

certainty to the compound nature of elements. This novel view becomes strengthened by the results of pyro-chemical researches. A new chemistry will arise as soon as we are enabled to experiment with bodies at a higher temperature than 1700° (Centigrade) the melting point of platinum used for crucibles. The author referred to the numerous trials of synthetical chemistry, and thought it likely that albuminous bodies —starch and sugar—would soon be prepared artificially by synthesis as the transformation of the wood-fibre into starch is the subject of assiduous trials and as the systematical increase of the albuminous components of plants has been proven—theoretically at least—by Hollriegel, it can be hoped that the science of chemistry will continue to materially enhance the prosperity and welfare of mankind.

A similar and equally interesting topic was that discussed by Prof. Hertz, of Bonn, viz.: the relations between light and electricity. Recent investigations have shown that electricity and light are closely allied to each other, and that the former, like the latter, is caused by an undulatory motion of ether. Faraday and Maxwell were first to make researches in this direction. The author himself claims the credit of having first demonstrated that light produces electrical phenomena, and that, *vice versa*, electric waves produce light waves. The author has overcome the difficulty of finding a sufficiently delicate means of measuring both kinds of waves by means of a swinging conductor with interrupted wire. If such a conductor is placed in the focus of a very powerful concave mirror, the conductor is seen to emit sparks and even to act as an electric polarizer.

Prof. Puschmann, of Vienna, read a highly entertaining essay on the importance of the study of history, especially of the history of the medical sciences, for the medical profession. The neglect of medical history has been very dearly paid for. Thus plastic operations, known already in ancient times, became forgotten and were in 1792 declared impossible by the medical Faculty of Paris, until at the beginning of this century they reached Europe again by the way of India. Similarly known in ancient time, then forgotten and ultimately rediscovered, were the ligation and torsion of arteries, flap amputations, and turning in delivery. The doctrine of the contagiousness of consumption, taught by Hippocrates, was forgotten, and our modern bacteriological schools had to rediscover it.

The treatment of consumption consisted in milk-cures, sea voyages, and the sojourn in Egypt—methods like those approved to-day. Auscultation of the chest was also practiced by Hippocrates. The crossing of nerve fibres in the brain was known to Artacus, who explained on this basis the paralysis on one side of the body in lesions of the opposite side of the brain. Pliny taught that, in cures for obesity, nothing should be drunk during meals and but little after them —a principle included in the modern obesity treatment. Nearly all remedies of importance used to-day were known to the ancients, even the fat contained in the wool of sheep, in which Liebreich found lanolin. Galen compared sound to a wave, and respiration to combustion. Even Darwin's doctrine of evolution was, in principle, taught by Aristoteles. It will thus be seen that the study of the history of medicine is by no means a merely entertaining occupation, but one replete with practically available results.

PERISCOPE.

Gastric Digestion.

At the meeting of the Philadelphia County Medical Society, October 9, 1889, Dr. L. Wolff read a paper on the Chemistry of Gastric Digestion, in which he said:

The gastric secretion which causes the chemical change of protein bodies into peptone has been closely studied by C. Schmidt, who determined the total chlorine therein, together with all the bases, such as potassium, sodium, calcium, magnesia, ammonium, and iron, and after accounting for the saturation of these had a residue of free hydrochloric acid left which amounted to about 2.5 to 4 grammes in one litre of the secretion. Although the pure hydrochloric acid has no peptonizing action, it alone can make pepsin display such a function, while again neutral pepsin has no digestive power unless coupled with this acid. While it is thus evident that the hydrochloric acid plays an important part in gastric digestion it has an equally valuable property by acting as an antiseptic and germicide over the ingesta when present in a free state. Miguel ascertained that 0.2 to 0.3 grammes of a mineral acid sufficed to preserve 100 c.c. meat broth

from sepsis, after Seibert had shown that 0.5 per cent. HCl prevented chopped meat effectually from decay. As had been proven in Hoppe-Seyler's laboratory that there existed in the normal gastric secretion 0.3 per cent. HCl, it would readily appear how the normal amount of HCl in the gastric juice will prevent the development of sepsis in the food bolus, while the presence of less than the normal amount will permit some ferment action, and the total absence will result in fermentation with production of organic acids which will not only not serve to develop the digestive power of pepsin, but will retard and prevent it.

The question of the production of such a strong mineral acid by the alkaline tissues of the stomach and from the alkaline blood can be only explained by the presence of chlorides in the blood, and the decomposition thereof in the secretory apparatus, with the elective osmosis of the ovoid cells which separate the acid to the interior of the gland while it sends back more alkaline blood to the circulation. It is a fact, well established, that weaker acids may replace stronger ones, and it appears a fair deduction that the alkaline hydrocarbonates of the blood become, under the influence of the secreting cell, neutral carbonates, by displacing from the chlorides the chlorine, which unites with the hydrogen so liberated to form hydrochloric acid. As to the intimate function of the secretory apparatus in the production of HCl, little is known, though it seems proven to a certainty by Heidenhain that the ovoid cells of the tubules of the peptic glands secrete the acid, for on the tubules of the pyloric glands no ovoid cells are found, and no HCl is secreted by them, although the secretion of pepsin by them is readily shown by the digestive test with addition of hydrochloric acid.

Porro-Cæsarean Section.

An interesting case of Porro-Cæsarean section, rendered necessary by a deformed pelvis, and a uterus enormously enlarged by fibroid growths, together with a cyst of the right broad ligament, is reported by Dr. John J. Black, of New Castle, Del., in the *Medical News*, Nov. 2, 1889.

At the conclusion of the report Dr. Robert P. Harris, of Philadelphia, adds the following remarks: "This operation of Dr. Black deserves a special notice, from the fact that it was the first Cæsarean section ever performed in the State of Delaware. That death should have followed it is not to be wondered at, when we consider that the subject was a rachitic dwarf, with a collapsed pelvis; and that her case was rendered far more serious by reason of the abnormal state of her uterine tissues. Women with uterine fibroids have been saved under the old Cæsarean, Porro-Cæsarean, and new Cæsarean sections, it is true; but the proportion has been very small, compared with that of the cases in which the uterine tissues have been free from disease. The Porro method can rarely be employed with advantage in cases of obstruction by uterine fibroids, because of the fact that the cervix is generally involved in the disease itself; and in the new Cæsarean the degeneration of tissue to be sutured is a serious obstacle to a satisfactory closure and an early union. Two Sänger and two Porro cases in Philadelphia, all fatal, attest the risk to life in operating on parturient women with obstruction by fibroids. There have now been performed, in all countries, 269 Porro-Cæsarean operations, with 122 deaths; the record of our own country is 11 cases, with 8 deaths—a higher mortality than any European country, except Scotland, which has lost 4 out of 5; Austria has saved 43 out of 61. Germany has lost only 13 out of her first 98 Sänger cases."

The Hypodermic Injection of Creosote and Guaiacol in Pulmonary Consumption.

Induced by the favorable reports of Schetelig (*Deutsche Medizinal Zeitung*, 1889, No. 16) on the subcutaneous injection of creosote and guaiacol, mixed with almond oil, Dr. Ludwig Polyák (*Wiener Med. Presse*, 1889, No. 40) determined to investigate the action of these agents in this disease, with a view of ascertaining whether the antipyretic effect which they manifested in Schetelig's experiments, could not be substituted for that of antipyretics which are in common use and the administration of which frequently leads to undesirable results.

He injected these agents one hundred and seventy-six times in eight cases and found that the minimum antipyretic dose of creosote was three and one-third grains, and the largest dose he administered was seven and one-half grains. The doses of guaiacol

were practically the same. The antipyretic action of both was prompt. Immediately after the injection profuse hydrosis set in and in the course of half an hour the temperature sank from one to one and a half degrees centigrade, and attained its lowest point in two hours. In one case the temperature fell six degrees. Four hours after the injection, the temperature rose rapidly to a point higher than it was before the injection, and this was accompanied by rigors. Large doses had no marked effect on the fever, when this was rising. He observed no difference in the action of the two agents. Their undesirable effects are: profuse sweatings, rigors, and sudden temperature oscillations. No collapse was observed at any time; and, although the expectoration diminished slightly in four cases, and the appetite and digestion improved in two, the author is doubtful if these good effects can be attributed to the drugs, and on the whole finds nothing encouraging in their application. Besides their injection is very painful and very often followed by local inflammation in the skin of the abdomen—the seat of their introduction.

Aborting Abscesses.

Apply a yeast poultice to the affected parts, upon which equal parts of borate of soda, boric acid, salicylic acid and powdered tannin should be dusted.

A moderate dose of calomel should be given internally. This treatment is usually sufficient to abort an abscess if it is resorted to when the local symptoms first make their appearance.

Frictions with the following ointment will also be found valuable:

℞ Salicylate of bismuth . . . . 2½ drachms
Lanoline . . . . . 7½ drachms

—*Le Bulletin Méd.*, September 29, 1889.

Recent Deaths at the Pasteur Institute.

Even those who do not agree with Dr. Pasteur's views regarding the pathology and therapy of rabies, must admit that the Institute is at least honest, for it faithfully records all deaths which occur during or after the treatment. Although quite a startling number have already been published, we find, in the *Bulletin Médicale*, September 29, 1889, three more added to the list.

The first, a man 28 years old, was bitten July 6, and the wound was cauterized an hour after. He was admitted to the Institute on the ninth of the same month, was treated, and discharged on July 29. He was attacked with unmistakable symptoms of hydrophobia on August 16, and died on the nineteenth.

The second case was that of a girl, thirteen years old, who was bitten May 23, and who was treated at the Institute from May 25 to June 8. Symptoms of rabies appeared on the eleventh of July and she died on the fourteenth.

The third case, a boy seven years old, was bitten August 5, and admitted for treatment at the Institute on August 9. Symptoms of hydrophobia were first noticed on the twenty-sixth of the same month and the child died from rabies on the thirty-first.

Hernia in Children.

In a paper published in the *University Medical Magazine*, November, 1889, Dr. Edward Martin and Mr. W. G. B. Harland state that although there is no surgical subject upon which statistics are more comprehensive and accurate than that of hernia, the literature upon this affection as it occurs in early life is comparatively meagre, and, judging from our experience in out-patient departments, the treatment is not generally outlined as clearly in the minds of physicians as is the treatment of rupture in the adult.

The hernia most frequently found in children is the inguinal, on the right side, in the male. The common predisposing cause is a congenital patulous condition of the tunica vaginalis or serous sac, which accompanies the testicle in its descent. Dissections have shown that this sac is more commonly found open upon the right side than upon the left. Swasey (*American Journal of Obstetrics and Diseases of Women and Children*, Vol. XIII, No. 3, July, 1880) suggests that the disproportionately heavy liver of early life may also be a factor in causing raptures to appear more frequently upon the right side.

The exciting cause of hernia in children is commonly crying, coughing, or straining. As an example of the latter, it was noticed in dispensary practice that tight phimoses and hernia were frequently associated, and Kempe (*Lancet*, July, 1878) calls attention to the same fact. Against this, it must be

admitted that phimosis was observed in probably the majority of patients examined for a great variety of surgical affections.

Umbilical hernia is, in proportion to the number of cases, found more frequently in the female child; and for this fact we have been able to find no adequate reason assigned. Femoral hernia is exceedingly rare in infancy and childhood; in the statistics we have collected from the records of the Children's Hospital, and from the books of a prominent truss manufacturer of this city, we have not found a single case. The reason for this is satisfactory: a narrow pelvis, a short Poupart's ligament, large muscles, and complete closure of the space are all factors distinctly antagonistic to the production of this form of protrusion.

From tables prepared at the Children's Hospital, Philadelphia, it appears that, in the first ten years of life, 44 per cent. of all cases occur during the first five months after birth, and that 68 per cent. occur within the first year. Although this differs from the results of statistics compiled from the records of the truss makers, it is probably more according to facts, since it is well recognized that the ruptures of very early life are frequently not discovered, or, if properly diagnosed, are either not treated at all, or are treated by means of compresses and bandages.

Though the number of cases recorded is comparatively small, it is large enough to show the frequency with which female children suffer from umbilical hernia. While, in 1,078 males it is found 116 times, a ratio of 1 : 9.3, in 264 females it is found 76 times, a ratio of 1 : 3.6. Swasey's figures, taken from a large number of cases, are still more striking. While the ratio in male children is 1 to 20, in female children it is 1 to 2.66. This fact is not generally recognized in the standard text books of surgery, the statement that males are more liable to this form of hernia being generally credited.

Another point worthy of notice is the frequency with which umbilical hernia occurs in early life, and hospital records are more to be trusted in showing this fact than the records of the truss companies, since the treatment of this affection can be satisfactorily conducted without ordering a special apparatus. Thus while the Children's Hospital Dispensary shows that the ratio of umbilical to inguinal hernia is as 1 to 2.1, the truss manufacturers' records give this ratio as 1 : 9.5.

The treatment of hernia in early life should be instituted the moment the hernia is discovered. The belief in non-interference, in the trust that the defect will be outgrown, is universal among the laity, and not rare in the profession. This is more evil in its consequences than would be the same doctrine if applied to adults, since, in the one case, prompt and proper treatment offers a very good chance for permanent cure, while in the other, palliation is all that is accomplished under the most favorable circumstances.

Reduction and permanent retention, practically summarize the treatment of hernia in infancy and childhood. In the case of inguinal or fermoral hernia, a hard rubber truss, the spring of which is not too strong, should be applied immediately after reduction, and worn day and night. The skin should be protected by frequent bathing with alcohol, after which it should be thoroughly dried, dusted with zinc oxide or ordinary infant's powder, and further protected, if necessary, by a small pad of absorbent cotton. *The truss must be worn day and night, and the hernia must never be allowed to descend.* Under this treatment the physician need not hesitate to give a favorable prognosis.

Umbilical hernia is best treated by first reducing, then bringing the recti muscles as closely together as possible, placing a flat piece of cork the size of a silver dollar, or a compress of lint, over the umbilicus, and applying rubber adhesive plaster of such a length as to go almost completely around the body and hold the muscles and compress in proper position. A conical cork should not be thrust into the umbilicus, as this tends to keep the opening patulous. In addition to this dressing a tight binder should be applied.

Antifebrin in Sore Throat.

Dr. W. Sahli, of Langenthal, highly recommends the internal use of antifebrin, in the dose of from four to eight grains three times a day, in diphtheria and in scarlatinal and other forms of sore throat. The drug has not any marked influence on the course of the disease, but it rapidly (in about a quarter of an hour) and completely removes such subjective symptoms as painful swallowing and mastication, faucial soreness, headache, etc. It may be given either in pow-

der or in a mixture with alcohol and syrup. The latter form is especially useful in children. No disagreeable accessory symptoms were ever observed.—*British Medical Journal*, Oct. 12, 1889.

Conditions of Intra-uterine Infection.

Infection of the fetus before birth is a recognized fact, but it is, perhaps, too readily assumed that infective material may pass from the maternal into the fetal blood by the normal channels of embryonic nutrition. Dr. Romeo Mangeri, of Catania, believes this to be impossible. As the result of wide study of the literature of the subject and of original experiments, he has come to the conclusion that no formed elements naturally pass out of the mother's blood into the fetal circulation. Cinnabar, Indian ink, carmine, and other materials were injected into the jugular veins of animals advanced in pregnancy, but in no case could any trace of the substance employed for experiment be found in the fetus. Passage of formed elements can only occur when the maternal placenta becomes diseased by inflammation, hemorrhages, etc.; so that the walls of the villi are destroyed. Only under these conditions can septic or specific organisms pass from the mother into the blood of the fetus.—*British Medical Journal*, Oct. 19, 1889.

Creosote for Diseases of the Air Passages.

In a paper on the value of creosote, in the *Virginia Medical Monthly*, October, 1889, Dr. Wm. Perry Watson, of Jersey City, N. J., describes its use in fifty cases of disease of the air passages.

Of these unselected cases eight were patients in the last stage of consumption; and while improvement was noticed for a few days after the creosote treatment was used, yet it had no permanent effect.

Of the sixteen cases with simply consolidation, the improvement was so marked in all cases but two (one complicated with chronic Bright's disease and one with consolidation at both apices), that they were discharged from the hospital.

Of the six cases of chronic bronchitis, some with emphysema, others with pleural thickening, all were markedly improved by the treatment.

Of the five cases of acute bronchitis, all were rapidly cured.

The case of acute pleuritis, with effusion was quickly cured.

The cases of laryngeal phthisis were improved.

The case of acute laryngitis was cured by the inhalations alone.

The cases of nasal catarrh, as a complication, were quickly cured.

The conclusions he draws from a study of his cases are, that while creosote will not cure all cases of consumption, yet it will benefit nearly all; that in cases with simply consolidation before the "breaking down" process begins, it seems to arrest the diseased process, and further investigations will be required to ascertain its permanent utility, although similar cases observed for a long time by Robinson and Flint would convince us that improvement was lasting.

In acute and chronic diseases of the bronchi, its use was very marked, cases of the former being quickly cured, while those of the latter were improved sufficiently for them to leave the hospital in a short time. Another very important fact noticed in these experiments was that the more constant the inhaler was worn, and the internal mixture taken, the more marked was the improvement; so that I am satisfied that, to obtain the full benefits of this treatment, the system should be saturated with the creosote as rapidly as possible; and while I should not expect any miraculous cures, yet I believe it is, combined with good hygienic and dietetic surroundings, the most promising treatment of consumption in the laboring classes we yet possess.

A Dog with Half a Brain.

A most interesting physiological experiment was one recently performed by Dr. Goltz, of Strasburg. It consisted of relieving a dog of the entire left hemisphere of his brain, taken out piecemeal during the course of a month. The dog seemed but slightly inconvenienced by his loss; his voluntary movements were not impaired. The right paw was evidently weaker than the left, but when his food was covered with earth and straw and his left paw held, he would uncover the food with the right one. Some rotatory troubles were also observable.—*Bulletin Médicale*, September 15, 1889.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

NEW OPERATION FOR PROLAPSE OF THE RECTUM.

The management of intractable cases of prolapse of the rectum is one of the most difficult tasks which the surgeon can meet with, and a variety of procedures have been proposed, with the design of making the task less trying. Unfortunately most of these are difficult of performance, and none of them are of very great utility. Under these circumstances, it is of more than ordinary interest to find a new method, which gives promise of decided usefulness, and which, in the single case in which it has been used thus far, has proved entirely successful.

The credit of this proposition belongs to Dr. Jeannel, of Toulouse, and the publication of it to the scientific world to Professor Verneuil, of Paris. At the meeting of the French Academy of Medicine, October 8, 1889, Professor Verneuil read an elaborate report on a communication of Dr. Jeannel, in which he described the method he had adopted, and recommended it in the warmest terms to the notice of his fellow-Academicians.

As described in this report, the patient of Jeannel was a woman, 57 years old, who had suffered with prolapse of the rectum for years, with displacement of the other pelvic organs, and in whom the usual surgical procedures were of no service. After finding them to fail, Jeannel conceived and executed the following operation. He opened the abdomen in the line usually employed in for inguinal colotomy, searched for, and found, the sigmoid flexure, drew it out at the wound, and supported it with a piece of catheter covered with iodoform gauze, passed through the mesentery, after the method of Maydl. This manœuvre reduced the prolapse completely, and in five days there was a stool from the anus, without any reappearance of the prolapse. On the sixth day Jeannel opened the bowel, and completed the formation of an artificial anus. After this, the stools were passed from both anuses, and the woman rapidly regained her strength and good spirits. Seven months later the natural anus had almost completely recovered its normal position and shape.

Verneuil, in describing this operation, gives a very interesting account of the principles which should govern surgeons in attempting to correct the conditions of prolapse of the rectum, and points out the admirable way in which they are followed in the operation of Jeannel. He also points with gratification to the measure of success which has attended the new operation.

It is possible that he looks too enthusiastically upon the merits of this method, but it cannot be denied that it has much to recommend it upon general principles, and that the success which followed its employment justifies the hope that—perhaps with some modifications—it is calculated to yield excellent results.

TREATMENT OF PUERPERAL MASTITIS.

Puerperal mastitis being a disease of comparatively frequent occurrence, and one which has so painful a course, and which may produce such serious results, the necessity for correct views concerning its etiology, pathology, and therapy is apparent. As is well known, the old view was that mastitis was due to cold or injury, and that it was greatly aggravated and often produced by milk retention. The treatment logically resulting from this doctrine was the frequent application of the child to the breast, the use of the breast-pump, friction with the hand from the periphery to the centre of the breast—one or all, as the patience of the sufferer would allow. In addition, perhaps an ice bag, or a poultice was applied, or a handkerchief-sling used for support, or belladonna ointment was rubbed into the breast, and a saline purge was administered, followed by anodynes, and rest in bed. The results obtained by this method are generally believed to be unsatisfactory.

With the advance of modern investigations into the etiology of inflammation, mastitis came to be regarded as an infectious inflammation, the point of infection being usually fissures or ulcers of the nipples, the route being in rare cases the intact milk ducts. This doctrine was prominently set forth by Billroth. About this time Harris advocated the use of the roller-bandage, properly applied over the breasts, together with rest in bed, and rest from nursing, as the ideal method of treating mastitis. He supported his views by reporting (in the *American Journal of Obstetrics*, January, 1885) numerous cases successfully treated by this method. This treatment was favorably noted in the REPORTER, April 28, 1888.

In the hands of other men the same favorable results have been obtained. In the experience of one experienced practitioner in the city, for five years past, not once has abscess resulted when the bandage was properly applied. A cold abscess was eventually opened in one case, in which an indurated mass was present for ten days prior to instituting treatment. When at at the same time nipple lesions are properly treated, this method certainly gives ideal results. Quinine, salines, and the bromides, given internally, are useful adjuvants.

Recently there are signs of a return to older views. Garrigues, of New York, while an ardent advocate of compression, both as prophylactic and curative of mastitis, favors emptying the breasts under certain restrictions. Parvin, also an advocate of the compression-bandage, considers that in some cases it may be best to empty the breasts; because the retained milk may undergo fermentation and prove a secondary source of irritation.

In the *Medical News*, August 31, 1889, Dr. Eugene F. Cordell advocates, in the treatment of mastitis, a return to the use of of hand-frictions, and the methodical emptying of the breast—preferably by the nursing infant, and in some cases by the husband, nurse, or breast-pump. He bases his advocacy of this method of treatment upon the fact that during the very considerable time he has employed it, no parenchymatous abscesses have occurred in his practice.

This statement, coming from Dr. Cordell, is of great importance, and its results have surely been all that can be desired. But it is difficult to understand the *modus operandi* of the treatment. No surgical principle is more firmly established than that an inflamed organ must have rest from function. Who would prescribe frictions in acute orchitis, or walking in acute inflammation of the knee-joint? No better reason for stroking an inflamed breast, or for permitting the continuance of nursing, or the use of the breast-pump, in this condition, is apparent, and the advocates of such treatment, in mastitis, must produce sound evidence of its necessity and value before it will be adopted by the profession at large, and especially by those

who have found such good results to follow the intelligent use of the compression-bandage, after the plan recommended by Harris.

TREATMENT OF BURNS WITH SOZIODOL OF POTASH.

Some time ago a long article was published by Dr. Mundy, in one of the Vienna medical journals, regarding the value of iodoform applications in the treatment of burns. The treatment was extensively adopted and excellent results reported, and the subject was fully discussed at the recent Congress on Dermatology and Syphilis in Paris, as stated in an Editorial in the REPORTER, Oct. 19, 1889. Now, however, Kaposi warns against the indiscriminate use of iodoform, claiming that although its anodyne properties are excellent, it does not prevent suppuration and frequently toxic symptoms, such as restlessness, rapid pulse, delirium, collapse, and sometimes even death are directly ascribable to the use of the drug.

Many practitioners have favored the use of carbolic acid solution as a local application, but Billroth, of Vienna, objects to the use of this drug, claiming it to be dangerous.

A newly recommended preparation for the treatment of burns is soziodol, which is antiseptic and anodyne, and does not provoke suppuration or involve any danger, so far as is now known. Chemically, soziodol is the sodium salt of diodparaphenolsulphonic acid—a name too inconvenient for general use. The salt prepared with potash has been named soziodol of potash, and this is very warmly recommended for the treatment of burns by Dr. Ostermeyer. In an article in the *Deutsche med. Wochenschrift*, October 10, 1889, Ostermeyer describes the method he employs as follows: The blisters produced by the burn are opened and their contents are removed with sterilized absorbent cotton, then a mixture of one part of soziodol of potash with ten parts of powdered starch or talc is freely dusted over the seat of the burn, and a cotton dressing and roller bandage are applied. The beneficial action of the preparation is usually observed in a very short time. The pain at once disappears, and within twenty-four hours the process of healing may be expected to be well advanced, and this without any suppuration.

Ostermeyer's experience has shown him that, even when very large surfaces are exposed, there is absolutely no danger of poisoning from this drug; further also that it is equally adapted to the treatment of burns produced by cauterizing chemicals and to ordinary burns or scalds. Finally, a most important feature of the treatment is that it leaves the patient with little or no scar.

CONFECTIONERS' DISEASE.

A disease, peculiar to confectioners, has been recently observed in France. It occurs principally in persons engaged in the manufacture of candied fruits and "maron glacés" or candied chestnuts. Five cases observed by Dr. Albertin, of Lyons, and described in the *Gazette Hebdomadaire*, March 19, 1889, well illustrate the nature of the disease. The affection is restricted to the nails of the hands, and usually first makes its appearance at the sides of the nails, the periungual portion becoming loosened and raised up, the nail losing its polish and becoming black. In more advanced cases an inflamed swelling appears at the base of the nail. The nail is rough, scaly, and in some cases broken in several fragments; but is never cast off in its entirety. Finally the terminal phalanx also undergoes a change in form and becomes flat and widened. In the earlier forms of the disease very little pain is experienced and the patient is able to go on with his work. The disease disappears as soon as the work is discontinued, although a deformed nail and a flat or bent terminal phalanx is apt to remain. Albertin states that among the large

number of candy factories which he has visited, he has not found one in which from one to three workmen were not suffering with the disease.

It is evident that the affection is caused by handling and working in the various substances employed in the manufacture of candies, among which are mallic, tataric and citric acids. The hands are also alternately in cold and hot liquids; and this, as well as the manipulation of the preparations, by means of which the irritating substances find their way under the nails, may be regarded as causative factors.

Albertin has given the malady the name of "professional onyxis and peri-onyxis," and believes it to be exclusively restricted to confectioners. It would be interesting to know whether this disease exists in this country, where manufacture of candies is so extensive.

COLORED SOUNDS.

The readers of the REPORTER will recall the fact that their attention was called in an Editorial, January 28, 1888, to the experiments of Verga, in 1865, and to those of Baratoux, in 1887, in regard to the production of the mental impression of different colors by means of different sounds.

Very recently the Vienna correspondent of the *Medical Press and Circular* reports that Prof. Quincke, of Kiel, has been devoting himself to a careful study of this subject. He finds that when a trumpet is loudly sounded at the ear of a sensitive patient, he will immediately define the first color he sees as yellow. A vocal sound A will give the impression of black, while the vocal sound O conveys the sensation of red. This phenomenon he compares to the radiating pain of toothache, and the shoulder pain in case of hepatic affections, which are examples of peripheral excitation transferred to another path on its way to the reflecting centre, where it is received as a true impression. These interesting observations seem to confirm those already recorded by Baratoux, and to have a curious bearing upon important physical and physiological phenomena.

BOOK REVIEWS.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the REPORTER.]

CEREBRAL LOCALIZATION IN ITS PRACTICAL RELATIONS. By CHARLES K. MILLS, M. D., Professor of Diseases of the Mind and Nervous System in the Philadelphia Polyclinic and College for Graduates in Medicine, etc. 8vo, pp. 101.

This essay is a reprint of a paper read before the Congress of American Physicians and Surgeons, at Washington, D. C., September 19, 1889. It is one of the most valuable and scholarly contributions to the subject that has hitherto appeared. An abstract of the more important parts of the paper was published in the REPORTER in connection with the Report of the Congress, so that no review of it is needed now. Those interested in cerebral localization, however, will welcome the appearance of the essay in its present form, and will be glad to know that it can be obtained from P. Blakiston, Son & Co., Philadelphia, for a moderate price (60 cents).

ANATOMIE TOPOGRAPHIQUE DUODÉNUM ET HERNIES DUODÉNALES.
TOPOGRAPHICAL ANATOMY OF THE DUODENUM AND OF DUODENAL HERNIAS. By JONNESCO, Provisional Prosector of the Faculty, Interne of the Hospitals. 8vo, pp. 207. With 21 illustrations. Paris: *Progrès Médical*, 1889. Price, three francs.

The first part of this book consists of a communication made to the Anatomical Society of Paris, February 17, 1889. The author describes and figures the appearance of the duodenum in infancy and in adult life. In the former, the duodenum is ring-shaped, the ascending portion rising to the same level as the beginning of the descending portion, the head of the pancreas filling up the space between the two portions. In adults, however, the ascending portion does not rise so high, and the terminal portion is turned more to the left, the space between the descending and ascending portions being increased, as though from development of the head of the pancreas. This gives the duodenum more of a **U**- or **V**-shape. A good description of the fossæ of the duodenum is also given, three of them being distinguished.

The last twenty-seven pages are taken up with an account of duodenal and duodeno-jejunal, or meso-colic, hernias. These occur in the fossæ referred to. The first case was that of Neubauer, which was published in 1776. Leichtenstern, in 1878, collected forty-two cases of duodeno-jejunal hernia, four of the cases, however, being doubtful. The author quotes Treitz upon the etiology of these hernias and reproduces his general conclusions.

The book gives a great deal of information upon the subjects of which it treats. It should be consulted by all those interested in the rare hernias mentioned. The illustrations are excellent and the type clear and large.

RAPPORTEUR ESTHÉTIQUE DE M. CHARLES HENRY, permettant l'étude et de la rectification esthétique de toute forme.

THE ESTHETIC REPEATER OF M. CHARLES HENRY, for the study and æsthetic correction of form. 8vo, pp. 22. Paris: G. Séguin, 1888. Price, 20 francs.

In this little essay M. Henry has tried to solve the problem of the relative pressure produced by certain forms. The instrument for this purpose is called a "*Rapporteur esthétique*," and its object is to make it possible for agreeable forms to be produced at will and following certain fixed rules. It is expected by the author that the instrument will prove of value not simply in the industrial arts, where it will be used to show what is meant by the normal; but also in medicine, where it will gauge the normal or pathological character of vital reactions. It is also asserted that the instrument can be used to improve the handwriting, and at the same time to develop the rhythm of nervous action.

CERCLE CHROMATIQUE DE M. CHARLES HENRY, présentant tous les Compléments et toutes les Harmonies de Couleurs, avec une Introduction sur la Théorie générale du contraste, du Rythme et de la Mesure.

CHROMATIC CIRCLE OF M. CHARLES HENRY, giving all the Complements and all the Harmonies of Colors, with an Introduction upon the General Theory of Contrasts of Rhythm and of Measure. 8vo, pp. 168. Paris: Charles Verdin, 1888. Price, 40 francs.

The author asserts that no sensation or idea is possible without movement. To impose upon a subject a certain attitude is to suggest to him the correlative idea; it may, therefore, be affirmed that the psychical functions are the virtual movements of the living being. The author endeavors to show, further, that the living being is able to describe only cycles—circles described in a single direction—of a definite radius, expressing its diverse excitations by varying directions, virtual or real, of its force. A direction above or below, to the right or to the left, marks the agreeable or disagreeable nature of such excitations. Direction is therefore assumed as the representative element common to all sensation. When the directions differ more or less, at the maximum or minimum, successively or simultaneously, their function is that of *Contrast*. When they differ in certain angles, there is *Rhythm*. When they belong to cycles whose radius is too large to be described continuously, and the number of units of measurement of these directions, considered as the denominators of fractions of a cycle, are realizable continuously by our organization, there is *Measure*.

The author then takes up the problems of color. He shows how to determine the three fundamental prismatic colors, the four fundamental pigments, and constructs his chromatic circle; he lays down the principles of a rational polychromy, and deduces the phenomena of irradiation, and shows how to neutralize it. He then seeks to determine the illuminating power of different parts of the spectrum, and to fix the order in which the colors should be ranged with a view to visual repose.

The author has endeavored to make the same scientific analysis of color as has been already made of sound. The book will prove interesting and profitable reading to those who are interested in the subject and who are sufficiently familiar with physics and metaphysics to follow the argument.

Literary Notes.

—The Trustees of the Johns Hopkins Hospital have authorized the issue of a monthly publication to be known as the *Hospital Bulletin*. It will contain announcements of courses of lectures, programmes of clinical and pathological study, details of hospital and dispensary practice, abstracts of papers read and other proceedings of the Medical Society of the Hospital, reports of lectures and all other matters of general interest in connection with the work of the Hospital. Nine numbers will be issued annually. The first number will appear in November, 1889. The subcription price will be one dollar per year.

Notes and Comments.

Treatment of Functional Disorders of the Stomach.

At a meeting of the Philadelphia County Medical Society, Oct. 9, 1889, Dr. Frederick P. Henry read a scholarly paper on the diagnosis and treatment of functional disorders of the stomach. In regard to the latter, he said:

There are at least two kinds of pyrosis, one due to an excess of lactic acid and the other to an excess of hydrochloric; and the time-honored treatment of this symptom, without reference to its cause, has been the administration of sodium bicarbonate. The following experiment of Bourget shows that this drug, in the commonest form of pyrosis—that caused by an excess of lactic acid—is, at most, an evanescent palliative. To a patient with chronic gastric catarrh and dilated stomach, was given a certain amount of soup, some of which was withdrawn two hours later, and found to contain 1.68 per cent. of lactic acid and no HCl. It was then exactly neutralized with sodium bicarbonate and placed in an incubator. At the end of half an hour it contained 4 per cent. of lactic acid. It was again neutralized and about eight grains of sodium bicarbonate added in excess. At the end of an hour free lactic acid was found. On the other hand, HCl given during a meal was found to prevent the formation of lactic acid. This corresponds with the physiological fact that the lactic acid formed during the first half hour of digestion is speedily suppressed by HCl. Bicarbonate of sodium undoubtedly neutralizes any lactic acid that may be present in the stomach, but instead of preventing its further formation, seems to increase it by creating an alkaline medium

favorable to the growth of the organism of the lactic acid fermentation. Lactic acid pyrosis, therefore, is to be treated by the administration of HCl during, or immediately after, a meal.

Pyrosis hydrochlorica may be due to hyperacidity or hypersecretion. In the first instance, it is to be treated by the administration of an alkali several hours, from four to six, after a meal. In hyperacidity the gastric juice is abnormally active, its physiological work is soon performed, and then it expends its superfluous energies upon the unfortunate patient. Having waited until its work is done, it is rendered powerless for mischief by the administration of an alkali, just as in peptonizing milk we boil the mixture or place it on ice to prevent the process from going too far.

The most successful treatment of hypersecretion consists in the methodical washing out of the stomach, preferably just before the principal meal, and the administration of alkalies. The latter should be given in large doses, for, as is well known, the administration of a small dose of an alkali will be followed by an increased secretion of gastric juice. Thirst is often excessive in these cases, but water should not be allowed except in small quantities, as it tends to increase the dilatation which is usually present. When the sense of thirst becomes unbearable, it is better to obtund it, as Riegel suggests, by the administration of small doses of opium than to permit the ingestion of large quantities of water. The diet should, at first, consist exclusively of albuminous substances, as carbohydrates are only partially digested, and by their fermentation aggravate the disease. Dr. Roberts, of Manchester, observing a profuse flow of saliva in cases of acid dyspepsia, and believing it to be a provision of nature for relieving the surplus acidity of the stomach, recommends the use of substances that will provoke its secretion, such as gum lozenges containing a small amount of ginger, cayenne pepper, or pyrethrum. He has thus experienced relief in his own person and given it to others.

In cases of motor insufficiency, in addition to general hygienic measures, the vegetable bitters, especially strychnia, and alcoholic stimulants may be used with advantage. Klemperer found that both substances hastened the exit of food from the stomach.

The treatment of nervous dyspepsia must vary with the cause producing it. One case will be cured by restoring the uterus to its normal position, another by curing a chronic constipation or expelling a tapeworm; still another by allaying an irritation of the spine. A restricted diet, or one of milk only, which is always beneficial in catarrh, is of little or no benefit in cases of nervous dyspepsia. General supporting measures, massage, electricity, the bromide salts, and, if anæmia exists, arsenic and a mild non-constipating preparation of iron, such as the potassio-tartrate, are the chief indications. I believe also, from a limited experience of the measure, that lavage may sometimes be of decided service in soothing a hyperæsthetic mucosa.

Bromide of Potassium with Belladonna for Enuresis.

Mr. J. T. Richards writes to the *British Med. Journal*, June 22, '89, that two cases of nocturnal incontinence of urine of long duration in boys of 12 years of age, coming under treatment at the same time, have yielded in a striking manner to a combination of bromide of potassium with belladonna, after belladonna alone and other drugs had failed to produce effect. In the first case, the boy had been discharged, on account of the incontinence, from an orphan institution, where he had been admitted with a view to emigration. He had been an inpatient at Wirral Children's Hospital, Birkenhead, four years previously, for three months with "scrofulous cystitis, cured by accidentally induced acute cystitis from injections." At this time he was circumcised. The enuresis had lasted from infancy. When readmitted last February the usual precautions were taken to ensure regular emptying of the bladder at night. An enema was given before sleep, and was successful on the first night or two that it was tried, but not afterwards. Belladonna, iron, saccharin, nux vomica (up to ♏ x of the tincture thrice daily), and codeine were given successively, without even temporary effect. On April 15 he was ordered: pot. brom., gr. x; tincture of belladonna, ♏ x, every night; and this was at once effectual. From the time that he took his first dose until May 11 when he went home, and for a fortnight afterwards, when he was last heard of, no wetting of the bed occurred, excepting once, on April 20, when he had not been attended to as usual. At this time the dose of tincture of belladonna was increased to ♏xv.

The other case was that of an out-patient, where the habit was of equally long standing, and belladonna and nux vomica had been given without benefit for several months. On April 24 this patient was ordered: pot. brom., gr. x; tinct. belladon., ♏xx, every night before going to bed, with the same immediate effect as in the former case, which has continued without interruption to June 3.

Erysipelas Treated with Iodine.

Dr. Tichomirow recommends the employment of tincture of iodine as an external application in erysipelas, even in cases in which bullæ have formed. He paints the iodine over the affected part and its vicinity three or four times a day. The irritation caused by the treatment is easily allayed by the application of a little camphorated oil. Usually he found a couple of days sufficient to reduce the infiltration and to bring the temperature down to normal. A similar mode of treatment he also considers very beneficial in cases of boils and carbuncle Even after these have broken he recommends that the iodine should still be applied, the wound being cleansed from pus and a dressing of cotton-wool applied. — *New York Medical Abstract*, June, 1889.

Improved Hypodermic Method.

Dr. P. G. Udell, of Spencerport, N. Y., writes to the N. Y. *Med. Record*, Oct. 12, 1889: Every physician who employs the hypodermic method is aware of the fact that painful swelling and abscess not infrequently follow its use. This undoubtedly arises from the introduction of septic matter—because the method of antisepsis has not been rigidly applied to this simple surgical proceeding. The sources of infection are numerous. The syringe may be unclean; the needle may be foul; the hypodermic tablet may be composed of materials that undergo fermentation; the water used as a solvent may be impure; the spoon employed to prepare the solution in may furnish the septic matter, etc. I have for some time used a method whereby the above dangers may be positively avoided. In one of the compartments of my syringe-case I carry two small test-tubes, nested; the inner one is converted into a vial by closing the open end with a cork, and contains my hypodermic needles immersed in absolute alcohol. This agent sterilizes any septic matter that may be on the needles, and does away with the necessity of using a wire for maintaining the patency of the same; there is no rusting, and the needle is always aseptic. I frequently cleanse the syringe with a five per cent. carbolic acid solution. Having occasion to use it, I free the needle of alcohol by passing through it water that has been boiled. I now dissolve one of Wyeth's tablets in a few minims of boiled water, and for this purpose carry the second test-tube, in which water may be boiled quickly over any flame that may be convenient, a match answering the purpose very well. After the solution is sufficiently cooled, it is drawn into the syringe, and is ready for use. The above plan may seem somewhat fussy in detail, but in practice is exceedingly simple, and, if followed as directed, should relieve the physician of those mishaps so annoying to himself and patient. If some instrument-maker will materialize this idea, it will involve but slight increase in size of the pocket-case now in use.

Curious Transmission of Scarlet Fever.

The *Boston Post* is responsible for the story that in 1846, a boy, eight years old was taken down with scarlet fever, and died. One of the principal amusements of his illness had been looking over a large picture book. After his death this, with several other useful playthings, was packed away in a trunk. Twenty-six years later, in 1872, the trunk was taken to England. The trunk was opened the second day after its arrival, and the picture book was taken out and presented to a boy two years old. During the next fortnight the little fellow was attacked with scarlet fever. It was a wonder to the doctors who were called in consultation how the disease had been contracted, as there had been no scarlet fever in the town for years. At last it was suggested that the picture book might have transmitted the disease, and the medical men in attendance, on being told the facts connected with it, agreed that it had retained the poison for twenty-six years and then communicated it to the child.

This appears to be one of the instances in which scarlet fever from some unknown source developed coincidently with the handling of articles used by a patient who had the disease many years before.

NEWS.

—Forty-seven persons committed suicide in Berlin during September of this year.

—The State Medical Board of Minnesota is about to publish a complete list of the physicians of Minnesota.

—Edward B. Garrigues, one of the founders of the College of Pharmacy, of Philadelphia, died November 4, at the age of 94.

—The Semi-Annual meeting of the Medical and Chirurgical Faculty of Maryland will be held in Hagerstown, Md., November 12 and 13.

—Professor Giuseppe Ruggi, the well-known Italian surgeon, completed his 200th case of laparotomy on August 1, and began his third "century" August 5.

—Dr. L. Webster Fox, who recently returned from England, was given a complimentary dinner at the Union League, November 7, by his professional friends.

—The Schuylkill Navigation Company has offered to supply the city of Philadelphia with pure water from the Schuylkill river by utilizing the canal of the Company as an aqueduct.

—The *Riforma Medica*, a daily medical journal published at Naples, has just received the first prize in the section of medical publications at the Exhibition of Hygiene and Medicine recently held at Padua.

—The opening meeting of the D. Hayes Agnew Surgical Society was held in the Chapel of the University of Pennsylvania, Nov. 2, 1889. Addresses were made by Dr. William Pepper and Dr. D. Hayes Agnew.

—The Philadelphia Cremation Society is pleased with the action of the Committee on City Property, which has recommended to Councils an appropriation of $3,000 for a crematory in which to burn the city's unclaimed dead.

—The Imperial German Government has taken upon itself the duty of providing part of the funds requisite for the coming International Medical Congress, to be held in Berlin, August, 1890, to the extent of 80,000 marks. It is expected that the Prussian State Treasury will be still more liberal.

—General Armstrong, formerly Consul General at Rio de Janeiro, was at the State Department November 4, having just arrived in this country. He says the fears of a yellow fever outbreak in the ports of Brazil referred to in the REPORTER, November 9, are unfounded, that the prospects for a good season are bright.

—One of the Dispensary Physicians of the Woman's Homœopathic Hospital was held, on November 6, in five hundred dollars bail for Court, upon the charge of practicing as a physician without having registered. The physician in question had applied at the Hahnemann Medical College for endorsement, but was refused, as her diploma was that of an eclectic.

—Commissioner of Pensions Raum has announced that hereafter in all cases where a medical examination is desired or required under any of the several pension laws such examination must be made by the local Board of Examining Surgeons in the district in which the claimant resides. Hereafter the Washington Board will not be allowed to examine claimants for pensions whose residence is not within its jurisdiction.

—Dr. I. N. Love, of St. Louis, announces that in January, 1890, he will issue the first number of the *Medical Mirror*, which will present, monthly, original papers and an epitome of current literature, domestic and foreign. It is stated that the *Mirror* will not hesitate to be personal if necessary, but nothing unkind or unjust shall knowingly ever enter its columns. The subscription price will be $2.00 per year, in advance.

—During the present month several distinguished bodies have been or are to be entertained by the University of Pennsylvania. On Tuesday last the delegates to the Pan-American Congress visited the institution and partook of a luncheon. On November 12, 13, and 14 the National Academy of Sciences held its annual session at the University, and on November 29 and 30 the College Association of the Middle States and of Maryland, and the Folklore Society, of America, are to hold their annual sessions at the University.

—On November 4, the Grand Lodge of Free Masons of Pennsylvania laid the corner-stone of the new building of the Philadelphia Polyclinic and College for Graduates in Medicine, on Lombard street, below Nineteenth. The ceremonies were opened with a brief address by Dr. Richard J. Levis, President of the Board of Trustees. The fund for the perpetual endowment of a free bed in the Polyclinic, in the name of and as a testimonial to Dr. Levis, was then presented. A copy of the MEDICAL AND SURGICAL REPORTER was placed in the corner-stone.

THE MEDICAL AND SURGICAL REPORTER

A WEEKLY JOURNAL

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER,
N. E. COR. 13th & WALNUT STS., PHILADELPHIA.

ENTERED AS SECOND-CLASS MAIL MATTER AT PHILADELPHIA P. O.

WE OFFER

"PEPTOGENIC MILK POWDER"

as a means of modifying cows' milk quantitatively and qualitatively to the ascertained composition of normal mothers' milk.

Cows' milk with this Powder and the directions given yields a "humanized milk" which in chemical constitution, physical character and taste approaches very closely to human milk.

"PEPTOGENIC MILK POWDER" is designed for the sole purpose of preparing from cows' milk an adequate substitute for breast milk. It has been prepared upon the basis of comparative analyses of cows' and human milk, and its prime pivotal factor is the transformation of the caseine and other albuminoids by a digestive ferment into a form in which they remarkably agree with those designed by nature for the food of an infant.

This being accomplished, there remains no necessity for the intervention of any inert or foreign substance, or of the crude expedients hitherto employed in the attempt to overcome the inherent unfitness of cows' milk as a substitute for mothers' milk.

We do not, under any circumstances, offer "PEPTOGENIC MILK POWDER" as a Food. We do not manufacture an Infant Food.

We offer a means and a method by which a mother may, from cows' milk, cream and water, prepare a physiological substitute for breast milk.

FAIRCHILD BROS. & FOSTER,
82 & 84 FULTON STREET,
NEW YORK.

EVERY PHYSICIAN

prescribing Cod Liver Oil (and who does not?) wants to know that his patients get the best that can be obtained. This is effectually secured by specifying **" BAKER'S "** whose firm (established in 1830) have given the greatest attention to the improvement and perfection of this all important remedy. In the various conditions in which Oleum Morrhuæ is indicated the Practitioner must decide the best form of administration. To meet such conditions we offer:

BAKER'S COD LIVER OIL.

BAKER'S EMULSION WITH HYPOPHOSPHITES OF LIME AND SODA.

Baker's C. L. Oil with Ext. of Malt.

Baker's C. L. Oil, Lime and Wild Cherry.

Above goods are accessible through the wholesale trade to all Retailers, and may be prescribed with the utmost confidence as to Purity and Excellence.

JOHN C. BAKER & CO., PHILADELPHIA, PA.

Physicians and Students of Medicine

are invited to attend the meeting of the

THERAPEUTICAL SECTION

OF THE

POLYCLINIC MEDICAL SOCIETY

AND THE

Lectures on Practical Subjects

by members of the Faculty, delivered under the auspices of the Society,

——On Tuesday Evenings——

throughout the Winter Course, at the College Building,

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders**, is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds**, handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe, and healthful Home.

Clinical Lecture.

LEUCOCYTHEMIA.[1]

BY HAROLD M. MOYER, M. D., CHICAGO,

LECTURER ON PHYSIOLOGY AND HISTOLOGY, RUSH MEDICAL COLLEGE, CHICAGO, ILLINOIS.

Gentlemen: This patient, which you see before you, was admitted into the Hospital on October 11, with the following history:

Family History:—Her father died of consumption. Her mother was sick for about six months, during which time she had convulsions, and in one of which she died.

The previous history of the patient states that two years ago she was sick for six months, after which she seemed to have been in a good condition for quite a while, then she noticed a swelling on the left side of the neck. About three months later she began to have headache, especially on the left side, and on rising in the morning was dizzy. She heard a ringing noise in the ears, at the same time felt weak and was unable to work. Eight months ago the menstrual flow stopped, and since that time she has lost a good deal in weight. She has a slight cough, which is worse during the night; appetite very good. Her feet began to swell about five weeks ago; and there is also pain in the bones. She has pain in the left shoulder which is worse during rainy weather.

I will now pass over the abdominal organs which reveal nothing of importance until we reach the left hypochondriac region. Here there is an area of dulness extending from one and a half to two inches beyond the costal arch. In this location a firm body can be indistinctly felt with a notch in its free edge. Liver dulness extends two inches below costal arch and to left of median line one and a half to two inches.

[1] Delivered at the Cook County Hospital.

I will ask you what that dulness in the left hypochondriac region is probably due to? What organ have we located there? The spleen. And the notch in its border is almost distinctive that it is the spleen which is enlarged. The liver, of course, is somewhat enlarged, but the other abdominal organs are negative in their examination. Ophthalmoscopic examination of the eye shows some infiltration of the retina; but no hemorrages or marked changes in the optic disc. Urine normal.

I will ask Dr. Hektoen (Pathologist to the Cook County Hospital) to present to you what he has discovered in the examination of the blood of this patient.

REMARKS BY DR. LUDVIG HEKTOEN.

The blood of this patient, when examined a week ago, showed no marked changes from the normal, either to the naked eye or under the microscope. Many authors regard it as necessary in order to establish a diagnosis of leukemia or leucocythemia, that the white corpuscles are in proportion to the number of the red as 1 : 20. There was no such marked relative change in number in this case, and the diagnosis seemed a little uncertain.

The investigations of Ehrlich, however, have resulted in material aid to the early diagnosis of leukemia. Examining into the affinity for *eosin* on the part of the leucocytes he found that in leukemia there is increased presence in the blood of white cells that become deeply stained with eosin; whereas in all acute leucocytes the number of these cells—*eosinphilous* cells as Erhlich has called them—are very few in number. In this case quite numerous eosinphilous cells were found. Under the microscope there was a preparation of the patient's blood made as follows: The tip of one of her fingers was made aseptic and punctured with a sterile needle and the drop of blood spread out evenly between two absolutely clean cover-glasses. These thin layers of blood were allowed to dry in the air upon the cover-glasses, then passed through an alcohol flame three times and dropped into absolute alcohol. After remaining in the alcohol for about an hour the cover-glasses were dried with filter-paper and a drop of concentrated solution of eosin in glycerine placed upon the prepared slides. After a few minutes the eosin solution was washed off with water and the cover-glasses mounted on a slide in oil of cloves; Canada balsam might as well have been used. We find now that the red blood corpuscles are colored reddish-yellow, or pink, that the neuclei of the white blood corpuscles are stained blue, and we find also a considerable number of large leucocytes which are filled with bright red granules looking very much like micrococci. These cells crowded full with red granules are the eosinphilous cells of Ehrlich.

Jahsch examined the blood of a large number of anæmic individuals and he found the granular red cells only occasionally. Only once, in a case of tuberculosis in a young boy who did not have leukemia, did he find them in considerable numbers. It seems safe to conclude, therefore, that when these eosinphilous corpuscles are found in considerable numbers in the blood they point quite positively to a commencing leukemia.

DR. MOYER (resuming): With the symptoms I have mentioned, and the remarks made by Dr. Hektoen regarding the condition of the blood, I think we may safely say that we have here a case of *lukemia*, or as it is termed by most of the English writers, "*leucocythemia*." You notice also that the clinical history is peculiar in its vagueness, that there were no definite or well-defined symptoms at the outset of this trouble. She speaks of pain and weakness. These symptoms gradually crept on, the patient's weakness increased, and very early in the disease there was an enlargement noticed upon the side of the neck, which you see. This swelling does not move when she swallows, therefore the enlargement is not connected with the thyroid gland. The lymphatic glands in the groin are enlarged. There is also another symptom: comparatively slight pressure over the sternum causes pain; and we have a tumor in the left hypochondriac region which corresponds to an enlarged, indurated spleen.

Now, any one of these symptoms is sufficient to direct your attention to the condition of the blood, and all three of them together, especially with the test which Dr. Hektoen has so admirably described, are sufficient to enable you to make a diagnosis of leucocythemia.

There is, perhaps, no field in which greater advances have been made during the last few years than in the pathology of the blood. You know the older writers in medicine had very vague notions regarding the function and the possible changes in the blood. At one time schools of medicine were estab-

lished and medicine taught upon the idea that the fluids of the body were exclusively diseased. These views were combated by other schools of medicine who believed in the theory that it was the solids of the body that were at fault. The warring of these two schools resulted in the development of other systems of medicine; all finally giving place to the cellular pathology, which is now generally adopted by most scientific medical men.

There are a great many different views prevalent in the profession regarding the diseases of the blood. Every issue of our daily papers contains numerous advertisements of blood purifiers. Only a few years ago the prevalent practice among the profession was to prescribe abundant blood purifiers in a vague and uncertain way, without knowing the conditions for which they were given. At the present time it is common practice to prescribe tonics. A patient presents himself with the statement that he does not feel well—depressed, weak, disinclined to exercise, and you give him tonics—iron, perhaps; it is probable that not one in ten of these prescriptions are based upon any exact symptomatology, or that the physician who prescribes the tonic could give any good reason for doing so. If you fully comprehend the physiological functions of the blood you will not be led into this error. Blood diseases that require tonics or alteratives are clear and distinct. If the blood is at fault you are able to detect it. If anything is added to it which ought not to be there, it will cause poisonous symptoms. If the blood is deficient in its cellular elements, or amount of hemaglobin, you can ascertain this and direct your remedies accurately to the relief of this condition. In this case we have purely a blood disease. There is a disproportion between the white and red corpuscles. Normally, we have one white to four hundred red corpuscles. This proportion varies greatly in patients, but when it reaches about one to twenty or thirty, then we have a distinct train of symptoms set up, such as you notice in the patient before you. We have wasting, weakness, more or less disorder of all the organs because of the blood supply being deficient in oxygen—all due to the fact that the red corpuscles are diminished. Understand that in this disease the red corpuscles are not affected, they contain the normal amount of hemaglobin and the other constituents necessary to the life of the tissues, but they are outranked by the number of white corpuscles that they are crowded out, as it were, by the enormous number of the latter, and their function is interfered with simply in that way.

This condition was first described by Professor Bennett. Most German writers, however, will state differently. They say that Virchow was the first to describe the disease. As a matter of fact, Bennett antedated the publication of Virchow's opinions on this subject about six weeks. We should, therefore, give Bennett the credit for first recognizing this pathological condition.

I am not prepared to commit myself as to the value of Ehrlich's reaction which has just been exhibited by Dr. Hektoen. The claim is made that by this test we are able to recognize this disease in its early stages, before there is enlargement of the spleen, lymphatic glands or relative increase in the number of white blood corpuscles. If this is true the test is of great value, as success in treatment, if reached at all, must be in the early stages.

Most authors speak of three forms of this disease, according to the organ that is primarily affected. When the spleen is early involved we have the splenic variety; when the glands are first enlarged, the lymphatic, and when the bones seem to be the primary seat, the myelogenous. There are others who entirely discard these divisions and who believe that the disease always begins in the bones or spleen, and that the other changes are only secondary.

In this case we have enlarged lymphatics, tenderness over the bones, and an enlarged spleen. The enlargement of the lymphatic glands is said to have been the first disturbance in this case. I do not believe in the primary origin of this disease in the lymphatic glands, for we have diseases in which these glands are enlarged—Hodgkin's disease, for example, but as far as I am aware no one has reported any increase in the number of the white blood corpuscles in the latter disease.

Success in treatment depends on the early recognition of the disease. Arsenic has greater power in this and allied conditions than any other drug. It seems to directly affect the cellular elements of the blood. It may appropriately be combined with cod liver oil and tonics. Sometimes good results are obtained from the use of large doses of quinine in the splenic variety of the disease. There is not much to look for from

treatment in a case such as this. The disease has advanced too far to permit us to hope that we may restore the altered conditions found in the blood.

One very interesting point is the possible relation of the disturbance in the red marrow of bones to the blood formation. You doubtless know it is an accepted doctrine of hematologists that a large proportion of the red blood corpuscles are formed in the red marrow. The red marrow is usually affected in these cases, but whether secondarily or primarily is still a disputed point. I think the weight of evidence is in favor of its primary affection; that is the leucocytes are not simply collected mechanically in the red marrow, but there is an actual overproduction, a disturbance in the normal process of blood formation, which possibly is the primary seat of the disease.

Concussion of the Spine.

This patient was admitted into the Hospital on September 30. Three weeks before he had fallen from a height of some sixteen feet and struck upon the left side of the chest. Two days after admission he noticed numbness in his hands, weakness in raising the arm, and shortly after this difficulty in walking.

Physical examination reveals loss of patellar-tendon reflex; some loss of pain sensation in the hands as well as in the feet, less marked in the latter. The patient drags the feet in walking. He feels pain in both the upper and lower extremities. He complains of pains in spots over the thighs and forearms, pain resembling the pricking of needles. Constipation is a marked symptom, and is obstinate. The pupils react readily to light.

I wish to call your attention, especially in this history, to the mixed character of the symptoms—pain in certain spots, a prickling sensation, an impairment of sensation to pain, great prostration and other symptoms which go to make up a clinical picture which differs largely from those of any systematic disease of the nervous system. These symptoms, we are told, came on a short time after a fall from a height of sixteen feet. There was no injury to the back or fracture of the bones of the spinal column. The injury was followed by partial recovery, and these symptoms came on secondarily.

This symptom-complex has received the name of spinal concussion; a very erroneous term, by the way, and one that has furnished a theme for much discussion. It occupies the attention of our courts to a considerable extent and furnishes a considerable proportion of suits for personal injuries brought against railroad companies. A collision has occurred; a man has been violently thrown from one portion of a car to another, and when he gets up he apparently recovers from the immediate effects of the injury. He goes to his business, but after a few weeks have elapsed he begins to suffer from pains, from a disturbance of sensation, accompanied with great weakness, loss of muscular power, tenderness especially over the region of the spine—in short, such a clinical picture as we have presented in the case of this patient.

Erichsen in his book on "Concussion of the Spine," puts this down as being due to shock to that organ.

Page takes exception to Erichsen's statements, and has published many cases antagonizing the views of the latter, stating that concussion of the spine is a disease which cannot possibly take place in that way; that the spine is protected from injury by thick, bony, and ligamentous walls, and is contained in a cavity surrounded by fluid and padded with fat and soft tissues, so that this pure type of concussion of the spine cannot possibly take place. Here medical men have stood for some years vibrating between these two opinions.

When one of these cases comes to trial, the parties interested have experts who testify to geometrically opposite views. One expert says the symptoms are probably due to hysteria, or something else, while the plaintiff has an equally skillful and reputable physician who will contend that it is spinal concussion due to the injury.

Here we have a case which probably does not involve any pecuniary element. We have a man who is suffering from the symptoms mentioned, and so far as we are able to ascertain, he has no reason for feigning any of them. Page contends that these symptoms are largely feigned, but I do not think that can be true in this case. You see, that with the single exception of the loss of patellar-tendon reflex, we must rely entirely upon the statement of the patient for the other symptoms; the paræsthesias, loss of pain sense and other material factors, are purely subjective phenomena, in which we may be deceived. It is this feature of these cases, that renders their diagnosis so difficult; unlike most medical cases, the

patient has a direct pecuniary interest in appearing worse than he really is.

Upon the single examination made to-day we are hardly justified in assuming that we have a pure type of spinal concussion. But from the appearance of the man, the indistinct clinical picture, and the absence of other lesions we feel safe in making a provisional diagnosis of spinal concussion.

I brought him to the ampitheatre to show the vague character of the symptoms and to impress upon you the necessity of exercising great care in diagnosticating these cases—for a blunder is easily made.

These cases are essentially chronic in their nature. The duration of the disease is marked by months and years rather than days or weeks. In the majority of the milder cases the tendency is toward recovery. In the severer forms the disease progresses steadily, the functional disturbances of the early stages give way to organic lesions, and death takes place from secondary degeneration of the cord and brain.

So far as drugs are concerned but little can be done for these patients. Rest is one of the most important factors; they should be kept in bed, and while there the nutrition should be provided for by massage and the local and general use of electricity.

Peripheral Neuritis.

We obtain the following history with regard to this patient: On the 11th of August, after sleeping in the open air all night the patient experienced pain and tenderness in the right leg with some impairment of motion, which lasted about ten days, and gradually disappeared. Four years ago he had typhoid fever, otherwise has always been healthy. There is some tenderness on pressure along the sciatic nerve; also pain in the hip joint on adduction and rotation of the thigh. Patellar-tendon reflex diminished; somewhat difficult for patient to control left foot, and when he stoops forward he falls down. No spinal tenderness discoverable; flattening in the right gluteal region.

We will ascertain the condition of the reflexes. I find a distinct reflex on the right side, but it is not so prompt as on the left. There is not apparent enlargement of the limb nor is there any change in the appearance of the skin; or thickening of the tissues.

The patient complains of pain in the right leg, which came on suddenly with impairment of motion, without swelling, incoördination, or absolute loss of reflexes. What does this mean? Have we spinal disease? If we have a thickening of the nerve trunk, would that be likely to cause a loss of the conducting power of the fibres, causing a certain degree of paresis? We would not have pain or swelling in the limb; we would not have necessarily a loss of the reflexes, but simply impairment of them. We would have, perhaps, a slight degree of pain, but not always, as this varies greatly. In some patients the pain is excruciating; in others it is slight. This may be termed then a peripheral neuritis. But there is one thing to be borne in mind in a peripheral neuritis of the lower extremity—namely, that the disease is very apt to extend upwards and involve the posterior spinal roots, and from there extend to the posterior and lateral columns of the cord, and produce secondary degeneration, particularly of the posterior column. Cases of neuritis in the lower extremities are very apt to terminate in a topical form of ataxia. Perhaps this is a premonitory symptom in many of these patients. I venture to state that the great bulk of ataxic patients who are alleged to be cured by any form of treatment belong to the class of peripheral neuritis. The diagnosis between locomotor ataxia and this condition is very difficult, not to say impossible sometimes. Therefore, I think we are justified in assuming, for the present, at least, that this patient has a peripheral neuritis of the sciatic nerve, and the probabilities are that it will extend upwards and eventually involve the cord.

—The deepest bore-hole in the world, claimed at different times for a number of places, is, according to latest accounts, at Schladebach, a small German village near Leipzig. It measures 1,748.4 metres, or about 5,735 feet. The time expended in boring to this depth amounted to six years, at a cost of $52,500. A peculiar experience encountered in connection with this and other deep holes in different parts of Germany is, according to *Uhland's Wochenschrift*, that the observed temperatures, while steadily increasing with the depths, show a smaller ratio of increase in the lower strata.

COMMUNICATIONS.

LOCAL TREATMENT OF THE ACCESSORY NASAL CAVITIES.[1]

BY JOHN NORTH, A. M., M. D., PH. C., F. S. SC. (LOND.),

PRESIDENT OF THE AMERICAN RHINOLOGICAL ASSOCIATION; PROFESSOR OF ORGANIC CHEMISTRY, ELECTRO-THERAPEUTICS AND CLINICAL RHINO-LARYNGOLOGY, NORTHWESTERN OHIO MEDICAL COLLEGE, TOLEDO, OHIO.

In our treatment of nasal diseases we come across a large number of symptoms of brain and mental origin. We find these symptoms very persistent. After using constitutional treatment, resorting to surgical interference, making local applications by sponging, and by other methods, we are still unable to relieve these symptoms, and the patient passes out of our hands and usually ends his career in an Insane Hospital.

Let us briefly examine the accessory nasal cavities. These are all lined with mucous membrane similar in structure to the nasal mucous membrane; they all open into the nasal fossæ, either directly or through induct methods. In the inferior meatus we have lachrymal canal. Inflammation extending up this canal gives rise to ocular troubles and to obscure pains in the face. In the middle meatus we have the openings of the antrum of Highmore and of the anterior ethmoidal cells. All are aware of the troubles we have with the antrum of Highmore. Into the superior meatus, we have opening the sphenoidal sinus and the posterior ethmoidal cells. When we have an inflammation of the sphenoidal sinus or the ethmoidal cells, we may have a great variety of obscure symptoms, such as an indescribable pain in the head with an inability to locate it; loss of memory, especially in regard to things occurring during the every-day life of the patient, etc. Schwable, Axel, Key, and Retzius have demonstrated the fact that, not only can the lymphatics of the nasal mucous membrane be injected from the subdural and sub-arachnoidal spaces, but if force be used the fluid will pass through the lymphatic canals to the surface of the nasal mucous membrane.

Professor Guye, of Amsterdam, has given the name of *aprosexia* to a condition that he finds associated with certain lesions of the nasal mucous membrane and obstruction to the passage of air through the nasal fossæ. In this condition there is mental disturbance characterized by an impossibility of fixing the attention on any subject, except for a very brief period, or of prolonged mental effort. He gives as an explanation that the lymphatic spaces beneath the dura mater have been found to be in direct communication with the mucous membrane of the nasal fossæ, and inflammation of the latter is supposed to interfere with the elimination of the waste products resulting from cerebral activity, thus leading to mental sluggishness.

These anatomical, physiological and pathological conditions will give an explanation to these obscure symptoms found in so many cases. Inflammation extending from the nasal fossæ up these mucous canals produce an inflammation of the lining membrane of these accessory cavities, or the inflammatory condition may begin in these cavities and extend to the nasal fossæ. With this inflammation we have the same local condition that we have in an inflammation of the nasal mucous membrane, namely, an increase of mucus, diminution of aqueous vapor, tumefaction, etc. These cases frequently require constitutional treatment. I find one of the best remedies I have used to correct the deranged nutrition of mucous membrane, to be the phosphate of sodium. At my request William R. Warner & Co., of Philadelphia, prepared an effervescing phosphate of sodium, containing thirty grains to the heaping teaspoonful. One heaping teaspoonful of this taken in half a glass of water before meals, has a good effect in unloading the arterioles of mucous membrane, and correcting the secretion or excretion.

If, after anterior and posterior rhinoscopy there is found any occasion for surgical removal of hypertrophied tissue, it should be removed. The spray should be used to wash away the mucus as far as possible. Watery solutions should seldom be used in the nasal cavities. As a wash, equal portions of milk and water, made alkaline by the addition of bicarbonate of sodium, can be used after being well warmed. This will be found an excellent mixture to thin and wash away the tenacious mucus. If there is much tumefaction of the membrane a two per cent. solution of resorcin in water can be sprayed into the upper portion of the nasal cavities. This causes contraction of

[1]Read at the Seventh Annual Meeting of the American Rhinological Association, Chicago, Oct. 11, 1889.

the membrane and an emptying of the blood vessels. Resorcin will not dissolve in vaseline, and I have found a watery solution the best for this purpose. A few minutes after the resorcin has been used, an iodized hydro-carbon should be sprayed into the nasal cavities and the spray made to reach the accessory cavities. The iodine has the effect of thinning the secretion and causing the absorption of the hypertrophic tissue; and in reaching the accessory cavities it greatly modifies the inflammation of the mucous membrane of the cavities.

The entire nasal cavity should be thoroughly sprayed with the iodine preparation of vaseline before an attempt is made to medicate the accessory cavities. With the De Vilbiss spray an application can be made to every portion of the nasal mucous membrane. All these preparations should be used as warm as the patient can conveniently bear them. By our ordinary method of using the spray producer in the nasal cavities, we only come in contact with the mucous membrane covering the nasal fossæ proper. I have been able to spray the vapor into these accessory cavities. I take a De Vilbiss or Rumbold spray-producer and slip a soft rubber nasal piece over the end of it. Then I have the patient empty the lungs, while I introduce the spray-producer with the nasal plug into the nostril so that it fits snugly. I then compress the other nostril, and have the patient attempt to fill the lungs by a combined forcible abdominal, intercostal and clavicular inspiration. By this method the air is drawn from the nasal and accessory cavities, and a partial vacuum is thus produced. While in this condition I throw the spray into the nasal cavity, and it is forced into the accessory cavities. Any one can try this upon himself and prove the correctness of it. I also apply the iodine spray to the Eustachian tube by means of the spray-producer and nasal plug, having first washed out the naso-pharynx with the alkaline milk and water wash, and then draw the mucus out of the Eustachian tube by emptying the lungs, holding the nose, and making the effort above described, to fill the lungs. This will suck out the secretion from the Eustachian tubes. After a few minutes the spray tube and nasal plug are introduced in one nostril, the other being compressed. Then the spray is turned on and the patient asked to swallow. This opens the orifice of the Eustachian tubes and the vapor is forced in the tube. I have used this method in a number of cases without any bad results in any case.

I wish to mention the effect of iodine upon vaseline and other petroleum bases. Iodine will dissolve in vaseline, but the solution is not a mechanical solution, but a chemical one. The petroleum fats are hydro-carbons of the marsh-gas series, with the general formula of C_nH_{2n+2}. Iodine coming in contact with these, displaces an atom of hydrogen from the group, and the iodine takes its place and forms an iodide of the alcoholic radical. The displaced hydrogen combining with another atom of iodine forms a molecule of hydriodic acid (HI). After this compound has been made for a few hours, it will not respond to the starch test for free iodine. Yet, in spite of this chemical change, this compound is useful in hypertrophic conditions of the nose and throat. Iodine will dissolve in the oil known as *albolene* without undergoing decomposition, and will respond to the starch test for free iodine. This is preferable to the vaseline compound where free iodine is required. The proportion of iodine in either vaseline or albolene is one or two parts of iodine to the thousand of vaseline or albolene.

DIPHTHERIA.

BY J. D. OSBORNE, M. D.,

NEWARK, N. J.

Diphtheria is a specific, contagious infectious disease, characterized principally by epithelial changes in and exudation upon, and into, mucous membrane, on the surface of wounds, etc. Then we have pseudo-diphtheria (tonsillitis), follicular stomatitis, pharyngitis, etc. We do not believe they are all the same, and yet they are so allied and their symptoms so intermixed and entangled, that it is our duty to look for a possible danger in each. I find it hard to believe that a case, beginning as a slight cold in the morning, growing worse through the night, and destroying life within two, three, or four days with the horrors of asphyxia—and another instance where a family of children, living in a room containing a sink connected with a closed cesspool, from which foul gases were bubbling back continually, have frequent attacks of fever with a scattered deposit in the tonsils,

and who recovered in a few days under quinine treatment—are cases of the same disease we are now considering; yet in view of the cases reported and the hundreds of others that will present themselves to your minds, where the mild tonsillitis seems to communicate the grave diphtheria, or where one child dying of membranous croup leaves behind it an infection, that destroys the life of another with the most malignant form of diphtheria, we have only one thing to do, and this is to look upon all such cases with suspicion, report them to the board of health, and by means of isolation and disinfectants, do all we can to confine its limits.

I shall add some conclusions in regard to the cause and treatment. It seems to me that all advanced scientific investigation points to the bacterial origin of the disease and that all our efforts should be directed to the destruction of these organisms and to the limiting of their development. After all that has been said and written, I think I may come to the conclusion that the disease is caused and propagated by these living germs. In 1880, Jacobi writes, "at present it seems altogether improbable that bacteria have any direct function in diphtheria;" yet in 1888 he writes to the *British Medical Journal* on the subject of treatment by mercury, and says: "My conviction of the utter uselessness of internal medication in laryngeal diphtheria—or so-called pseudo-membranous croup—is thoroughly shaken. Never have I seen so many cases of tracheotomy get well as since in 1887, when I began to use it." Again he says, "Perhaps the most useful of all remedies in laryngeal diphtheria is mercury. I prefer the bichloride. Until I began to use it six years ago, I felt certain of a mortality of 90 per cent. in all cases I operated upon. I have within the past thirty years seen at least 1,000 cases, and during the past six years have seen no less than 300 cases, the patients being from four months old upwards. The treatment consisted in the internal use of bichloride every hour—the smallest daily dose given by me in the beginning was ¼ grain to ½ grain in children from 4 to 5 years of age, given in dilution of one in ten thousand. Tracheotomy can often by avoided if the mercury be given in time."

Going back a little on the subject of treatment we find the profession still looking for something they can trust. Remedies are almost as numerous as are the investigators, but one thing is agreed upon by all: sustain the system, and if possible enable it to throw off the poison. If called early, before constitutional effects have shown themselves, as in a fair proportion of times is the case, attack the disease locally with agents known to have the power of destroying the bacillus. The agents most in use for this purpose are, sulphurous acid, or what perhaps is as useful, a strong solution of sulphite of soda, fumes of sulphur in the room, peroxide of hydrogen, turpentine, eucalyptus, lactic acid, permanganate of potash, persulphide of iron, bichloride of mercury, and later on, for local application, by brush, spray or steam, eucalyptus, lactic acid, dilute sulphurous acid, trypsin, and vapor of lime. At no time, if there are nasal complications, are they to be neglected; and very frequent cleansing of the nares by injections of antiseptic solutions is indispensable, while, throughout the disease, stimulants, milk, beef juice, and tincture of iron and quinine are to be continually given. I desire to call attention to two or three agents in closing, and these bear particularly on the question of antisepsis both locally and internally. Bichloride of mercury has been already alluded to. Another agent frequently reported favorably upon of late, is the decoction of the leaves, or the oil, of eucalyptus. Several observers have claimed to have seen marvelous results produced by inhaling the vapor from the leaves in hot water as well as by its internal administration, and claim for it great germicidal power. It certainly deserves further clinical investigation.

Another agent reported most favorably on of late is the peroxide of hydrogen—for topical use, as a spray to the mouth, throat, and nares. It is pronounced capable of destroying the bacteria and preventing absorption and secondary effects; destroying the contagion and limiting the extension of the disease. While this agent may be of use where it can be obtained readily, its use must be limited on account of the difficulty in procuring it. I have found the use of the uniform official strength, which is recommended (15 volumes) and which seems necessary to the destruction of the bacteria, impossible because it can only be found at wholesale drug shops in 5-pound bottles, which on being opened immediately lose their strength. To be effective also a stronger force of spray is necessary than the ordinary atomizer gives.

The last agent to which I shall allude is sulphur.

Among the few remedies that seem to have secured a permanent place in the treatment of diphtheria is sulphur, although Professor Jacobi as late as 1880 dismisses it with scarcely a notice. It seems to me that it demands a further and most careful trial, and promises as much, if not more, in return for our efforts than any other agent in our possession. Its remarkable antiseptic properties were known to the most ancient writers, and it is the only agent that has stood the test of ages. Our Boards of Health know they can depend upon it, as upon no other agent, to disinfect house and ship and clothing and person. Where the small forms of animal or vegetable life are found the fumes of burning sulphur are known to be destructive. Taken into the stomach it is eliminated by the bowels, the lungs, the skin, and the kidneys in the form of hydrogen sulphide—it stains the linen next the skin and darkens metallic substances carried in the clothing. Its destruction of the mildew—on the vines of the grape—seems to have first called attention to it as a possible remedy in diphtheria. Since that time it has had its up and downs, its advocates and opponents. Marvelous cures have been attributed to its use, and local benefits have been ascribed to it by those who denied its internal value. I have been on several occasions struck by the apparent benefit derived from its use in pneumonia, all its grave symptoms disappearing quickly after its purgative action had taken place. In a case of syphilitic abscess, where a young man also had chronic naso-pharyngeal catarrh, its use as sulphide of calcium, for the cure of the abscess, resulted in permanent cure of the catarrh, as well as the abscess. If there is any agent that will act as a prophylactic to scarlet fever, I think it is the continued internal use of the sulphite of soda, and I am sure it has proven efficacious when belladonna has failed entirely. The sulphite or bi-sulphite in solution also proved itself a most useful agent in erysipelas. Perhaps its best form for local use is sulphurous acid. This acid is a disinfectant and deodorizer, it attacks organic matter with energy, owing to its affinity for oxygen. It is very destructive to the lower forms of life, viz.: bacteria, fungi, etc. It should be slightly diluted in the form of spray or applied with brush. Powdered sulphur is also of very great power; clinging to the throat and nose, the heat of the body causes it to give off fumes which continue the local effect. Sulphite of soda or the bi-sulphite, ʒss to ʒi to the ounce of water, may also be used with the atomizer or brush. Internally it may be given as sulphide of calcium, sulphite of soda or perhaps better, by small doses of the sulphur itself, which is converted in the intestines and circulation into the hydrogen sulphide (sulphuretted hydrogen). Sulphur will destroy every species of fungus on plant or animal, beast or man. It is eliminated entirely in about five days. Great tolerance is manifested in the remedy, and while the diseased condition exists neither diarrhœa nor colicky pains are produced by moderate doses, and when these symptoms supervene it shows it is time to decrease or discontinue its use. A good way to give it is with glycerin and water. It may also be given by inunction, better still in syrup or honey, or by packing the limbs in the powder. In conclusion let me add that science seems to be looking in the direction of this agent for the destruction of other forms of bacteria, as witness the recent efforts to destroy the bacillus tuberculosis by gaseous enemata of hydrogen sulphide (sulphuretted hydrogen), or more recently the placing the patient in a closed room and making him inhale the fumes of burning sulphur. When sulphur is taken into the stomach, either as a powder or in its other forms, the warmth of the body causes it to give off these same fumes, and I see no reason why a complicated apparatus should be used when the stomach can be made its own laboratory for generating this gas. It is readily absorbed and penetrates the solids and liquids of the body.

I wish to add that, in the *Medical Record*, December 19, 1888, Dr. Hubbard, of New York, recommends for the local treatment of diphtheria Vleminckx's solution of the sulphuret of calcium—an old and cheap remedy for scabies.

—To expel mosquitoes, take of gum camphor a piece about one-third the size of a hen's egg, and evaporate it by placing it in a tin vessel and holding it over a lamp, taking care that it does not ignite. The smoke will soon fill the room and expel the mosquitoes, and they will not return, even though the windows should be left open all night.—*Scientific American.*

LARGE DOSES OF IODIDE OF POTASSIUM.

BY AUGUSTUS A. ESHNER, M. D.,

RESIDENT PHYSICIAN AT THE PHILADELPHIA HOSPITAL.

As an item of maximum therapeutics and individual tolerance, it may be of interest to report the case of a patient in Dr. Dercum's wards in the Philadelphia Hospital. The man presents a group of symptoms which might be vaguely designated as those of spinal syphilis; symptoms of spinal and bulbar involvement in some degenerative process—vascular, neurogliar or columnar—conforming to no type of systemic disease of the cord. He has ataxia; his knee-jerk is preserved, though deficient; he has an awkward, impeded speech; his pupils are equal, regular, and respond to light, while the accommodation is unimpaired. His sensation is normal, and he has no derangement of the sphincters, and no discoverable loss of muscular power.

Beginning with ten grains of iodide of potassium, the dose was gradually increased until the patient took one hundred and seventy grains three times daily. By an inadvertence he was once given four hundred and forty grains at a dose, which he failed to retain, vomiting at once and complaining of a dull heavy pain in the epigastrium, which persisted in some degree for two days. The patient now takes one hundred and seventy grains of the iodide three times a day. There have never been present more than the mildest manifestations of iodism, a few acne papules, slight rhinitis, laryngitis, and bronchitis. The patient expresses himself as being subjectively better, but there is no decided improvement in the symptoms.

Examining the urine, to determine whether the iodide was perhaps causing renal irritation, it was observed that, in overlaying concentrated nitric acid with the urine, a rusty brown zone resulted at the line of contact gradually diffusing itself upward through the urine and after which fine particles dropped to the bottom of the tube. Now, again overlaying the urine with solution of starch the characteristic purple reaction of the so-called iodide of starch at once appeared. Other tests for iodide were applied: acetate of lead, bichloride of mercury, and nitrate of silver, to all of which ready responses were obtained.

There are, in the wards, other patients taking large doses of iodide of potassium: one, a hundred and thirty grains; one, a hundred and twenty; two, a hundred and ten; one, a hundred; one, ninety; one, fifty; and one, forty—all three times a day, and for periods of varying duration. In all of these cases the urine was examined and responded to the tests already mentioned. The specific gravity varied between 1.017 and 1.035, the higher number preponderating. All the specimens were of acid reaction. Two contained albumin in small quantities, but these contained pus corpuscles but no tube casts. None contained sugar.

In testing for albumin, the method by heat and acidulation was used, and the result was confirmed by the contact method with picric acid. The rusty brown zone from contact of the urine with nitric acid necessarily obscured the presence of small quantities of albumin; and large quantities as well would escape detection if the iodides were present in large amounts and the brown zone of contact dense. It is highly probable this latter is due to the iodine set free by the action of the nitric acid on the iodide and the combination of the iodine with water to form hydriodic acid.

REPORTS OF CLINICS.

PHILADELPHIA HOSPITAL.

CLINIC ON THE DISEASES OF WOMEN AND CHILDREN—DR. HIRST.

Death from Colic.

Dr. Hirst first mentioned the results of an autopsy upon a child that had recently died in the hospital. These results were completely negative, except for the enormous distension of stomach and bowels. During life this infant had shown signs of colic, and the usual remedies, such as the exhibition of hot brandy and water, carminatives, the use of the catheter in the rectum, and the application of the Faradic current to the abdominal walls, had been tried, but without success. Dr. Hirst believed that death had been brought about by shock caused by the colic, and recommended, as a last resort in such cases, the puncture of the intestine with a hypodermic needle. He said that this measure was

sometimes resorted to in the rare instances of exaggerated flatulence following labor cases and that its use was often necessary in animals, especially in sheep.

Infantile Catarrhal Nephritis.

The prevailing symptom in this case was that of somnolence, until late in the disease when convulsions occurred shortly before death. The true condition was not diagnosticated, therefore usual remedies in such cases were not employed. It was thought for a time that the lungs were congested. Seat worms were discovered and dislodged in large quantities by quassia injections. The true disease finally proved fatal, and it was only the autopsy that revealed congestion and inflammation of both kidneys. Dr. Hirst said that this disease was rare in infants. The difficulty of making a diagnosis in such cases is obvious: the importance of being on one's guard against overlooking renal disease in young children is as plain. It is a wise maxim in treating very young children that the lungs and kidneys should always be examined in cases of obscure disease. An element of obscurity in these cases is that the urine of new-born infants—and even of infants in utero—is usually albuminous, so that in making the diagnoses of nephritis, the albumin should be found in large quantities and the presence of renal desquamation demonstrated by means of the microscope.

The treatment recommended in such instances was that of active depletion by means of local bleeding, purging, and diaphoresis.

True Infantile Jaundice.

Dr. Hirst said that in new-born infants it was common to see cases of hæmatogenic jaundice that passed away in a few days without causing serious symptoms; but that there was such a thing as true hepatic jaundice in infants, and that when this occurred it should excite the physician's anxiety. Some of the causes of this latter disease are: defective circulation, resulting in an engorged liver; occlusion of the common bile-duct; sepsis, Buhl's and Winckel's disease. In this case there is no evidence of serious systemic disease, and, judging from the congestion of the extremities, the possibility of some congenital defect in the circulation should be entertained. The child was to be put in the incubator; a heart stimulant to be given in small doses and calomel was being administered.

Congenital Syphilis in Infants.

The next case shown was of especial interest on account of its serious nature, comparative frequency, and the importance of making a correct diagnosis. The infant was healthy at birth, but in a week it had the snuffles. Soon afterwards it exhibited on head, trunk, and extremities copper-colored spots, especially about the face and genitalia. It was remarkable that there are three grades or degrees of congenital syphilis. In the first the child is born dead. In the second class it is born in a miserable condition of deformity and disease, and is soon carried off by fibroid pneumonia, lack of vitality, or some disease of an important viscus. In the third class the child is born apparently healthy, and the disease first appears some days or weeks after birth, as in this case. That it is often well in such cases not to question either parent too closely, but to make the diagnosis by the child's appearance, and to proceed at once with the following line of treatment.

After carefully seeing to its hygienic management, the infant is to have twice a day one-sixteenth to one-twelfth of a grain of calomel in a little soda; or, if the child cannot from any reason take calomel internally, mercurial ointment is to be rubbed on the child's binder, which is then applied. In a few weeks the spots will disappear and the child seem well for a while. In order to completely eradicate the disease from the system, mercury and the iodide of potassium are to be skillfully administered with occasional breaks in the treatment for two or three years. The liver is subject to congestion in these cases, and such an infant should never be nursed by any woman but its own mother, lest the disease be communicated to her.

Large Mammæ in an Infant.

It was remarked that infants of both sexes usually had milk in their breasts precisely like woman's milk from the fourth to the tenth day after birth, but that sometimes the physiological hypertrophy and activity of the mammæ were much exaggerated, even to inflammation, and the inflamed gland tissue became purulent and exhibited a true abscess, that was to be opened as soon as discovered. That before the development of pus, lead water and laudanum were to be used with compresses, and the use of the poultice delayed until the formation of pus became imminent.

Abscess of the Ovary.

The next case was that of a woman who had borne several children. Since the birth of the last one—which occurred several years since—she had had menorrhagia and metrorrhagia, and also nearly constant pain in the left iliac region, which pain was greatly aggravated by motion. Dr. Hirst said that the principle cause of these pains was a previous inflammation in the pelvis, leaving pockets of pus or cicatricial bands holding the various viscera—especially the ovaries—in abnormal positions, thus causing them to be pressed or drawn. Examination here revealed a sensitive fluctuating tumor behind the uterus, which was probably an abscess in tube or ovary that in all likelihood had its origin in an attack of gonorrhœa, a clear history of which could be obtained. The infection occurred just previous to the birth of the last child. If she were rich, the palliative treatment would be advised, and likewise if she were very old. As she was young and otherwise healthy, a laparotomy was earnestly recommended, and would, with the patient's consent, probably be performed by Dr. Hirst in two weeks.

Infantile Catarrhal Pneumonia.

Dr. Hirst made an autopsy examination on the body of an infant four months old, that he said had been ill ten days before its true condition was discovered. The catarrhal pneumonia was found in the right lung and râles on both sides. He warned his hearers that, though high temperature was present in this case, he had seen other instances of this disease in which this symptom did not occur. Only the base of the right lung was affected and that mostly on the posterior part. The left lung, though anæmic, was otherwise normal.

The intestines were examined and slight remains of entero-colitis were seen. Dr. Hirst here remarked that the almost absolute prevention of this disease had been secured in the hospital by the introduction last year of sterilized milk and that since then the mortality among the foundlings had been greatly reduced. The liver in this child was normal in size and appearance and, therefore, he believed the infant was without venereal taint. While examining the heart, he mentioned that the foramen ovale is often found open some time after birth, and that he had seen many cases in which the ductus arteriosus remained patulous for months and even until the end of the first year.

Double Hæmatoma.

This was in a child one month old; the tumors were situated in the posterior and superior parts of both parietal bones. The hæmatomata were congenital, a rare anomaly. Dr. Hirst mentioned as a difference usually existing between caput succedaneum and this affection was that the former always appeared at birth, whereas that of hæmatoma commonly developed some days later. It was recommended in this case to avoid operative measures, as the sac was getting smaller and would probably disappear.

Fibroid Tumor of the Uterus.

This patient was a colored woman who twelve years ago had had her only child. This tumor had existed a long time, but excepting the loss of much blood at her periods of menstruation, its presence had not given much trouble until five months since, when she complained of having difficulty in locomotion and much pain in the hypogastric region. The tumor, in this case, reached nearly to the umbilicus. As the woman was poor, only 35 years old, suffering, and lately had been losing so much blood, Dr. Hirst recommended oöphorectomy, in order to stop menstruation and thus bring about a sub-involution of the whole uterus and thereby diminish the size of the tumor, or at least prevent its further growth. The ordinary medicinal treatment had been tried without success.

COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK.

VANDERBILT CLINIC.

MEDICAL CLINIC—PROF. DELAFIELD.

Irritable Colon.

The first case shown the class was a man, 34 years of age, a gasfitter by occupation. He complained that for several years he had had large loose watery stools coming on particularly in the morning and before 11 o'clock, and frequently following the ingestion of food. These attacks would come at intervals and recently have occurred with greater frequency. He complained of no other symptoms. On examination the pa-

tient was found to be poorly nourished, skin of bad color. There was no evidence of distension of either the colon or stomach. There was no enlargement either of the liver or spleen. The heart showed no evidence of disease, and the pulse was good. Examination of the mouth showed considerable accumulation of tartar on the teeth and a line on the gums, but not sufficiently well marked to indicate lead poisoning.

The secretion of urine was increased in quantity; sp. gr. 1.028; contained no albumin. Dr. Delafield considered this patient a sufferer from what has been called "Irritable Colon," associated, undoubtedly, with chronic catarrhal colitis, of a low form. Such cases, he said, were not of unfrequent occurrence, and were, oftentimes, difficult to cure.

The treatment must be continued for several months and the diet carefully regulated. In many of these cases it is found, as in this man, that the act of taking food into the stomach is at once followed by a reflex action in the colon. Dr. Delafield then detailed four methods of treatment: First, the simple washing out of the stomach every day. Many would improve very speedily and very markedly under this procedure whereas others would not be benefited by it at all. Second, an exclusive diet of beef and hot water. Giving a sandwich of scraped beef made with thin slices of bread or toast at 8 A. M., again at 12 M., 4 P. M., and 8 P. M., preceded an hour by a full tumbler of hot water. Third, the combined use of ipecac and belladonna; the dose of both should be increased to the point of tolerance. With this treatment the diet should be restricted. Fourth, give the following shortly before each meal:

℞ Sodii sulpho-carbolat. . . . . gr. xx
Glycerinæ . . . . . f℥i
Infus. quassiæ . . . . q. s. ad f℥ss
M.

And also restricted diet, such as beef or mutton and a few vegetables. For this patient he recommended the beef and hot-water treatment (and no drug) as being the easiest method to carry out successfully.

Chronic Alcoholism.

A man, 57 years old, a brewer by occupation, for two years had been troubled with vomiting of mucus, pain after eating and tenderness over epigastrium. He had been steadily losing strength and flesh—having lost 50 lbs. in weight. The patient called himself a moderate beer drinker. There had been no vomiting of blood and no jaundice. His urine had not been tested. Examination showed that the skin was of a bad color and flabby. The pulse very feeble and small and was felt with difficulty. The radial artery somewhat tortuous. The heart's impulse feeble and diffuse; the heart itself enlarged but no murmur audible. Resonance over the lungs emphysematous, and expiration prolonged. The liver was considerably enlarged both in upward and downward direction, and smooth to the touch. No enlargement of the spleen could be detected. Dr. Delafield, in summing up the physical signs found in this patient, remarked that here were several diseases but all due to one cause. The man had used beer to excess and was suffering from chronic alcoholism.

He had no lesion of the brain. The lungs showed emphysema, due to the feeble heart, rather than to any bronchial lesion. The heart was dilated and probably fatty. The liver also was enlarged and probably fatty. There was chronic gastritis. An examination of the urine would undoubtedly show chronic nephritis. Chronic alcoholism includes all these conditions and fully describes what the man suffers from. Treatment could offer very little for a patient in this condition, and at his age; in fact he would probably grow worse rather than better. The best plan would be to cut off his supply of beer and to limit him to one solid meal a day of beef or mutton and baked potatoes. As for drugs he should confine himself to a treatment directed to the heart symptoms alone, considering those the most important, using for that purpose the following combination, which experience has shown to be best adapted to such cases:

℞ Ext. Digitalis fl. . . . . ♏x
" Convallariæ fl. . . . . ♏xx

Potass. Iodidi . . . . . gr. v
M. et sig. Three to four times a day.

Endocarditis.

The third case shown was a boy, 15 years of age, who said he had been well as far as he knew until two months previously, when he was taken during the night with severe pain in his "stomach." The attack lasted about half an hour, and he had had several similar attacks since. During the first month of his illness he vomited his food soon after eating. He had had some cough, had expec-

torated a little blood, and on exertion was short of breath and had palpitation of the heart. The patient had lost a good deal of flesh. Examination of the urine showed a specific gravity of 1.010, and 2 per cent. of albumin. Further examination of the patient showed him to be much emaciated, with a bad color of the skin and paleness of the mucous membrane. Dr. Delafield called attention to his general appearance, which was plainly that of one suffering from a severe illness. His pulse was found to be fairly good, but inspection showed very clearly an exaggerated impulse over the precordial region and the heart was found to be enlarged. Presystolic and systolic murmurs were heard at the apex, indicating mitral insufficiency and stenosis. A few râles could be heard over the lower portion of the left chest. It was stated that the patient undoubtedly had chronic degeneration of the kidney also, but the real cause of his trouble was the heart lesion. He was suffering from an active endocarditis which was rapidly advancing. The patient was in no condition to be out and should be put to bed at once. Treatment for the present should be limited to rest, and a careful regulation of diet. Probably milk would be best to begin with, adding other things later on, if thought advisable.

SURGICAL CLINIC—PROF. BULL.

Lacerated Wound of Lip.

At the Vanderbilt Clinic, October 30, Dr. Bull showed to the class a number of simple cases. According to his custom he asked two students to examine each case, to detail the history to the class and to give their diagnosis and treatment. The first patient presented was a man, 46 years old, a laborer, who three weeks ago, when lifting a heavy can of ashes, slipped and fell. The can struck him in the mouth and inflicted a double wound of the upper lip, leaving a triangular piece of the lip attached by a portion only a quarter of an inch wide at the upper angle of the cut. He, at once, applied at a dispensary for treatment, and superficial sutures were introduced. In a few days these had pulled out and others were inserted. Again the wound failed to unite, and the triangle of the lip was cut off. The man now showed an inverted V-shaped solution of continuity of the lip, resembling very much a congenital hare-lip. Examination of the edges showed a partial scabbing, some infiltration, a little discharge, no bleeding, and no evidences of active inflammation. There were no constitutional symptoms.

Dr. Bull referred to the possibility of epithelioma invading such a wound in a person of the patient's age. In regard to treatment he said that the important fact to bear in mind was to endeavor to preserve as much of the lip as possible; and he would recommend scraping the sides of the wound and with the scissors cutting the edges of the integument, especially where it was turned in; and then holding the festered surfaces together by means of sutures carefully and deeply placed so as to afford support to the lip and to prevent the tendency of the orbicularis oris to draw apart the surfaces.

This would probably prove effective in removing the deformity. If not, the sides would then have to be thoroughly freshened with a scalpel or scissors and the same careful suturing used.

Acute Mastitis.

The next patient was a married woman, the mother of four children, who was at present nursing a child eleven months old. Four days ago she "caught cold," and her right breast became swollen and painful. Examination showed the breast to be much larger and heavier than the other. About the nipple (which was somewhat retracted) and for several inches below it the skin was red and shining, and painful; and all the breast was œdematous. The axillary glands on the right side were enlarged and tender. Dr. Bull, on looking for fluctuation, spoke of the necessity of supporting the breast—which is best done by having the patient lie down—in order to more positively determine the presence or absence of this symptom. In this case, unless care be exercised, the œdema might mislead and the existence of fluctuation be believed in. It was not present here, however, and yet the œdematous condition was pretty conclusive evidence that the inflammation was a suppurative one, and before long the presence of pus would declare itself. This patient denied that there was any lumping of the breast before the attack four days ago; and Dr. Bull remarked that this almost always takes place though it frequently may be overlooked. With regard to treatment, he

said that it was too late to milk the breast; what could be done was to place it at once in a sling, and to apply either cold or hot applications. If cold—ice; if hot—either poultices or fomentations containing belladonna; or better, with belladonna ointment smeared upon the breast. It is of importance to open an abscess in this location at the earliest moment, and the practitioner usually erred in this matter; for it is a fact that most abscesses of the breast are not opened sufficiently early.

Fracture of Ribs.

This patient was a man, 40 years of age, who yesterday, while returning from his work, was playfully punched in the side by a fellow-laborer. He felt pain in the spot at once, and has suffered therefrom since. His pain is caused by movement and by respiration, also by pressure over the eighth, ninth and tenth ribs, about three inches from their heads. Crepitus is distinctly felt on respiration and by pressure. In treating the case Dr. Bull preferred one large strip of rubber adhesive plaster five or six inches wide, and mentioned that the amount of comfort from such dressing in these cases was remarkable. In two or three weeks the strip could be removed.

There were other cases, he said, that were not benefited by this support; they were those usually in which five or six ribs were fractured. Bandages and plasters applied to them seem to increase the pain and the dyspnœa. Such dressing, therefore, should not be used. Simply keep the patient as still as possible and in a week or so, as soon as sufficient plastic material has been thrown out to confine the movements of the fragments, relief would occur. These cases were the exception to a very general rule, and it is well to bear in mind the possibility of this exception.

Hypospadias.

A boy, one year old, was brought to the clinic by his mother—as she said, "to see if he was all right in his privates." He was suffering from no symptoms; he passed his urine regularly and without pain. Examination showed an erythema intertrigo in flexures of thighs and about anus. The penis was found to present a long prepuce above but the lower part of the fore-skin and the frenum were missing. The under part of the glans was marked by a shallow groove. The meatus urinarius was found just internal to the corona glandis. The chief interest in such a case, Dr. Bull remarked, lies in being able to assure the mother that the child, though unusually formed will be undoubtedly none the less a competent man. The child at present has no trouble from his malformation and he is not likely to develop any.

Hypospadias exists in many degrees. Often the person afflicted possesses less urethra than this case—the meatus being further back on the body of the penis. This condition does interfere with the usefulness of the patient in reference to his duties to society. Such a man is likely to be impotent. These cases call for a plastic operation, unusually delicate. Several surgeons have suggested as many special operations but the exact indications in a given instance should be our guide in operating. Dr. Bull referred to two other conditions that in all cases of hypospadias might call for relief, viz., narrowing of the orifice of the urethra (shown by difficulty in urinating, etc.) which is easily remedied by meatotomy; and a tendency (in adults) of the penis, when in erection, to curve backwards, which may be relieved, not by exercise, but by operation.

Foreign Correspondence.

LETTER FROM INDIA.

Grant Medical College of Bombay.—Its Career.—Past and Present.

Bombay, India, September 9, 1889.

The great medical school of western India derives its name from Sir Robert Grant, the Governor of Bombay, who had endeavored to establish a system of educating the natives of India in English medicine. He died recently, and the school of medicine was opened, which took his worthy name. It is in the very centre of the most thickly inhabited part of the city, surrounded by an extensive compound. Its aspect is very awe inspiring, indeed! its extreme height, massive brick columns, and the quietude in its compound strikingly remind one of some of the old baronial castles in the Highlands of Scotland. All were invited to benefit themselves of this school when it was opened in 1845, but few took fancy at it. The native parents had a religious prejudice against dissection. The period of study

has ever since been five years. Those who passed the final examination used to be distinguished from the rest of the quacks by G. G. M. C., *i. e.*, Graduate of Grant Medical College. In 1859, the Bombay University was established, and the said College was affiliated to it; and though the curriculum of study remained the same, the quaint and queer G. G. M. C. was substituted by L. M., *i. e.*, Licentiate of Medicine. It was made compulsory that the medical students must first pass the matriculation examination, as prescribed by the University. This used to be considered at that time a stumbling block to many desirous of joining the College, and, as a consequence, hardly three or four students joined it. The professors used to complain that they had to lecture before the mere empty benches, and wished the Director of Education to expunge the obnoxious rule of compulsory matriculation examination. But the Director told them that, as it was a new experiment in India, they must wait and watch the tendency of the people towards the University and the College. Accordingly they did so—and did for the better, too! because there was a slow but steady increase in the number of the matriculated students, when in 1872 a fee of ten rupees (four dollars) was levied from each matriculated student by this very same College, which till then used to be a free institution, and which, but a decade ago, advocated the cause of non-matriculated, and non-paying students. The College has long since reached the zenith of its hope. It is now absolutely over-crowded and over-congested with students. Another college can easily be formed out of it. The rush of the students on leaving one class-room to go to another one to occupy its front seats to hear and take down the lectures better is—to say the least—an unpleasant sight to look at. This splendid College—strange to say—has but three lecture-rooms; yet, a splendid museum, and students' library, which, though but an offshoot of yesterday, is raised solely and exclusively by the exertion of Dr. J. B. Lyon for the benefit of the students. The good name of Dr. Lyon, who in his short career as the principal of the College brought on such splendid reforms in the College, as were never dreamt of by his predecessors, for as many years as this illustrious worthy had been for months, will ever be cherished in the heart of every student with extreme pleasure and pride. The constant rush of the students from one class-room to another, and the consequent uproar thereon, drew attention of the Faculty, who communicated with the Government to extend out its wings, and thereupon the College was extended. Very recently a medical laboratory is in the course of being established, of which a short notice has been taken by your valuable REPORTER of July 13, 1889, page 52, under the heading of "Notes and Comments." The College can well boast of a roll of its illustrious principals, of whom the pioneer was Dr. C. Morehead. He was succeeded by Dr. Pitt, and a few years after him came Giraud, Haines, and Balingall. After them came Dr. Hunter and Dr. Sylvester. Dr. Sylvester retired in 1873, and Dr. Hunter left the principalship of the College in 1876, to become Surgeon-General with the Government of Bombay. Dr. Hunter was succeeded by Dr. Cook as the principal. After his departure came the great scientific investigator, Dr. H. V. Carter; the same worthy who has made drawings in Gray's Anatomy. He stayed in the College from morning till evening, thus doing his duty conscientiously to the Government, and advantageously to the students. The College, the students, and the entire medical profession were extremely proud to have Dr. Carter amongst them. His boundless scientific attainment used to inspire awe and respect wherever he went. The College saw an extensive reform of entirely a different nature during the principalship of this worthy and illustrious physician. It was the inauguration of ladies' medical class. In this College ladies and gentlemen take instructions together in the same class-room and on the same benches. All honor to Dr. Carter. After the retiring of this worthy, much to the regret of the medical profession, came Dr. Lyon as an acting principal. As the opening of ladies' classes was by Dr. Carter, so the formation and raising of a "Students' Library" was the work of Dr. Lyon. In the short stay of six months, this illustrious physician brought on great reforms and changes in the College, for the benefit of the students. He got over some rich Parsee grandees to lay out a sum of several thousand rupees to buy out a medical library. It seems as if it is not given to Grant Medical College to use the best of its benefactors for a long time; because Dr. Carter and Dr. Lyon went off from the post of principalship in a very short period. The College has the busts of Drs. More-

head, Pitt, Haines, and Ballingall. Since their time there were none who deserved that sort of honor. Now there are two illustrious worthies who deserve the honor of their busts in justice and equity: they are Dr. Carter and Dr. Lyon; indeed, the College needs more Carters and Lyons. Dr. Lyon was fully entitled to become the permanent principal of the College, but Dr. Gray now enjoys this honor. Dr. Gray is the senior surgeon of J. J. Hospital (in connection with the College), and occupies the chair of medicine in the College. Heretofore the rule was, that the first physician of the hospital should occupy the chair of medicine in the College, and this is the first time in the history of the College that its principal is not a physician but a surgeon.

D. D. Bode, M. D., D. D. S.

New York Correspondence.

IN BELLEVUE HOSPITAL.

Clinic of Dr. Bryant, with some Statistics and Observations.—How Bubo is Treated.

New York, October 30, 1889.

Now that the colleges are in session, the clinics in Bellevue Hospital have been resumed. Among the professors who hold them are Drs. Stimson, Polk, Loomis, Thomson, Lusk, Bryant, Dennis, Janeway, Gouley and Stephen Smith. Few clinics are more largely attended than are those of Prof. Bryant. He is a fine operator, a good instructor, and has a genial, hearty manner that is much in favor with the doctors and students. His clinic last week was upon bow-legs and knock-knee. The case operated upon was one of extreme knock-knee in a child. The bones were straight, the deformity resulting from elongation of the internal condyles. Hence, said he, supracondyloid osteotomy was indicated. For this he has two guides: the spine of the internal condyle and the tendon of the adductor magnus, his incision being made in front of the tendon and one inch above the condyle. The incision should go to the bone, the periosteum being divided, and then, with the scapel for a guide, the chisel should be inserted. He cuts the bone partially through and finishes by breaking. There are two dangers: first, the chisel may be driven into the popliteal artery, and second, there may be an abnormal distribution of the anastamotica magna, which may be cut, giving rise to profuse hemorrhage. Neither danger is of consequence, with proper care. The deformity of the case in question was completely corrected by a simple "transverse osteotomy." Silk was passed through the wound for drainage, the incision was sewed up with catgut, and an antiseptic dressing was applied, bichloride of mercury being used. Buck's extension apparatus, with the leg at right angles with the body (for convenience), was applied. After three days Dr. Bryant dressed the leg, and, if everything is right, the limb is put up in a plaster of Paris splint. Sometimes the temperature rises to 103° and 104°, after such an operation, but if, on inspection, there is found no suppuration at the seat of operation and no pulmonary trouble, such as fatty œdema—which has been known to occur—the temperature should cause no alarm. It is sometimes the practice to wire the bones, but Dr. Bryant thinks this usually needless. He showed one case on which tibial osteotomy had been performed for bow-legs, the bones being wired. Necrosis of the bone, with two sinuses in the soft parts, one above and the other below the seat of fracture, was the result. He treated this case by cutting down to the bone, dividing and elevating the periosteum and thoroughly scraping away the dead bone. Then, leaving a sinus for drainage, he sewed up the incision in the periosteum and closed the external wound. Although he united the edges of the periosteal incision, he does not think periosteum is necessary for the formation of bone. On the contrary he teaches that any tissue in contact with bone will produce bone granulations. The children here affected with deformed legs are usually rachitic and their bones on division bleed profusely. The hemorrhage, however, is not dangerous, and soon stops.

In extreme curvature of the bones Dr. Dennis removes a V-shaped piece of bone. This, however, is not done in all the divisions of the hospital. In one service, in the last six months, twenty operations were performed for genu valgum and genu-varum; and, although some of the cases were as extreme as is possible, simple transverse division was all that was ever employed. Without exception every case was completely cured by one operation, and there wasn't one single complication. The rule was to cut down on the bones at the points of greatest

curvature, break them, unite the incision in the soft parts with catgut without drainage, apply an antiseptic dressing (bichloride), and over all immediately put on a plaster splint with the deformity corrected. Then the cases required no more attention till five weeks later when the dressing was removed, always to find a perfect result, the incision healing by primary union and the bones uniting firmly. Though in some legs both tibial and femoral osteotomy were done, and there were legs in which four fractures were made, there was not a case in which Macewen's operation—which invades the knee joint—was thought necessary. In these rickety charity patients, in whom a contusion often sets up an obstinate arthritis, it is thought dangerous to make a fracture implicating the joint, no matter how complete the antisepsis may be. Braces and such apparatus are never used in Bellevue.

There is a method of operating for bubo much used here, which, so far as I know, has never appeared in print. It was devised by Dr. W. N. MacArtney, house-surgeon of the First Surgical Division, and it has this advantage over the method of dissecting out the glands: that it is less dangerous, there is less hemorrhage, and the wound heals much quicker. The last is especially noticeable, in nearly all operations primary union being obtained, although foul venereal pus often escapes into the wound. The operation is simple and is as follows: An incision is made directly over the tumor and carried down until the sacs of the enlarged glands are incised. Then with the finger the glandular substance can easily be peeled out. The sacs are allowed to remain. The remaining cavity is washed out and the incision is sewed up, drainage being arranged for.

Experience in the Chambers Street Hospital demonstrates that chancroidal bubo can be aborted by the use of salicylic acid on the sore. Even after inflammation of the glands is far advanced, the powder causes it to subside. This is the routine treatment followed there in a very large venereal class, both for bubos and chancroid. No external application to the bubo such as tincture or ointment of iodine has been found to be of service. Ordinary cases of gonorrhœa are usually treated there as follows: for the first or acute stage, the urine is simply made alkaline by the internal administration of a solution of acetate of potassium; in the second stage, an injection of a mild solution of the sulphate of zinc is used. It is simple and works well. At the Post Graduate Hospital, a 1 per cent. solution of creolin is used as an injection in the acuter stage. In Bellevue an injection much used is a 1 in 10,000 solution of the bichloride of mercury.

PERISCOPE.

Is Hydrophobia an Infectious Disease?

Dr. N. E. Brill, of New York, in answering the question "whether hydrophobia exists as an infectious disease," in the *Medical Standard*, Nov., 1889, says that the more he examines the subject of lyssa the more he is convinced that this *bete noir* of human pathology does not exist in the race as a pathological entity; that persons bitten by dogs, rabid, or alleged to be rabid, exhibit a combination of grave symptoms, there can be no doubt; but that these symptoms are the result of an infection derived from the teeth and salivary secretions of the animal, admits of serious question. Of course an assertion cannot have any weight unless it be substantiated by a reasonable amount of proof. The following facts summarize the position taken by the writer:

First. All infectious diseases known to man have a distinctive set of symptoms, follow a certain course, and exhibit a fixed pathological basis. Can the same be said of lyssa? Whoever has examined cases of this alleged disease during life, and the organs of the affected individual after death, will be compelled to say: The symptoms of my cases corresponded in no particular except, perhaps, in the dread which all, or nearly all, my cases presented. The *post-mortem* record of all these cases presented absolutely no data on which to assume that an infection had performed its deadly work.

Four different varieties of bacteria have been described as being the cause of this disease. If observers were more numerous there would be no limit to the varieties of bacilli and micrococci which would be found in the blood and secretions of an individual alleged to be suffering from lyssa. Dowdesuree found a micrococcus, Motte and Protopopoff a bacillus, while Solles found a bacillus differing in shape from the former. When the number of varieties will cease is a question which, in the present state of bac-

teriological science, will not permit of an answer.

Secondly. All infectious diseases known to us have a constant period of incubation. Lyssa certainly has not. Numerous cases attest that the alleged period of incubation extends between a few hours and seventeen years. It may be said that syphilis shows this tendency; but who will say that the initial symptom of the latter disease can always be detected?

Thirdly. There are no constant and invariable signs of this disease. Neither is its course uniform nor is its clinical history. If these criteria, which would make a nosological entity of lyssa, were the fact, it would have a recognized stable pathological basis. The converse of this proposition is likewise true. For example, have the clinical or pathological histories of typhoid, smallpox and anthrax changed? Are they inconstant? And can the same be said of lyssa? What must we then infer? The only inference which can be drawn is that no infectious agency can be the ultimate cause of this disease.

And yet the bite of a rabid dog (and for that matter of a dog that is not rabid) is oft followed by fatal results. If there be no infection in the bite, what has caused death? Laying aside the numerous diseases which have been mistaken for lyssa, it is my opinion that the fatal results in all cases may be relegated to one of the following categories: Septicemia, tetanus, acute delirium (grave delirium, typhomania). The presence of either the first or the second of these classes may be readily explained. That of the third is not so readily. However, it is my purpose to show the chain of thought which induced me to place this third category in this classification.

It is a fact known to alienists that grave delirium more frequently follows intense emotional shocks than any other form of mental disease. Fear and dread, the result of the superstitious traditions which are attached to dog bites, are the predominant factors, to which must also be added expectant attention, in the production of the mental disturbance of lyssa. These disturbances correspond in all particulars to the clinical history of acute delirium. My belief is therefore that in the great majority of cases lyssa is but this form of insanity—an insanity which is known to be very fatal. It is not the infection of the bite which produces this form of lyssa, but the fear and expectant attention which the bite has engendered.

Salol in Gastro-Intestinal Derangements of Childhood.

Dr. Carr writes on the above subject in the *Archives of Pediatrics*, for September. In his own experience the drug was used in all the disorders of the stomach and intestine common to children, but with the most success in the cases of acute gastro-enteritis caused by improper diet or from temperature changes. The dose and mode of administration vary somewhat in different cases; the preference being to give the salol alone unless there is some particular reason for combining it with another agent. If the symptoms are those of acute gastro-enteritis with the vomiting of milk, or of other food, and the movements from the bowels are ill-smelling, loose, and quite frequent, the administration of salol, while maintaining perfect rest of the stomach and bowels, will be all that is required. Should the vomited material contain bile and the stools have a lumpy, clay-like appearance or be streaked with bile, the addition of a small quantity of calomel or of mercury and chalk will bring about a quicker relief. This may be explained, partially, by the effect of the mercurial on the obstructed ducts of the liver and pancreas.

When the movements of the bowels become frequent and the discharges serous, the effect of the salol, besides the neutralization of the disagreeable odor, seems to be almost negative. It is seldom that the watery motions are lessened by the salol unless given in combination with opium or bismuth. In dysentery and severe colitis salol exerts very little control on the tenesmus and bloody passages.

The dose of salol will depend much upon the requirements of the case. For children under six months one-half grain every two hours for three or four doses will be found sufficient; between the ages of six to eighteen months half a grain to a grain and a half; at two years a grain and half to two grains will usually be efficacious. The drug is best dispensed combined with some inert powder. Children take it readily if it is placed on the tongue or in a spoon. It never, so far as the writer is aware, causes toxic symptoms or any of the irritation of salicylic acid. Abstinence from food that would continue the irritation of the stomach

is of the same importance in the employment of salol as in the treatment of all disorders of digestion in children.

The conclusions drawn after the use of salol indicate that it is an easily administered, safe drug in the first stage of acute gastro-enteritis in children, and in the more chronic forms of entero-colitis, accompanied by slimy bad-smelling evacuations. In the acute condition it is necessary to keep the stomach at rest and administer two or three doses of salol within five or six hours. For the more chronic state of catarrh, it is best given in somewhat larger doses before meals. In frequent serous discharges and in colitis the salol does not produce the same good results as in the cases mentioned above, and its effect is uncertain, not being so rapid or so sure as an opiate. In dysenteric disorders it cannot be relied on.

It seems, then, that salol acts best in morbid conditions due to fermentation and decomposition in the stomach and upper bowel, and that it diminishes in power as it passes through the large intestine.—*Boston Med. and Surg. Journal*, Oct. 24, 1889.

A New Antispasmodic.

Formyl-para-amidophenolether is another new synthetical remedy that will probably soon be met with in commerce. It is not an antipyretic, but is said to affect the spinal cord. If its claims are confirmed it may prove useful in convulsive diseases.—*Chemist and Druggist*, October 26, 1889.

Reporting Typhoid Fever.

In Michigan typhoid fever is a disease which the State Board of Health has declared to be "dangerous to the public health," and as such it comes under the law requiring physicians to report to the Health Officials. Any physician who shall neglect to immediately give such notice, "shall forfeit for each such offense a sum not less than fifty nor more than one hundred dollars." And since October 1, "*any householder* who shall refuse or willfully neglect immediately to give such notice, shall be deemed guilty of a misdemeanor, and shall be liable to a fine of one hundred dollars, or in default of payment thereof may be punished by imprisonment in the county jail not exceeding ninety days."

The *Med. Age*, October 10, 1889, says that this law applies to scarlet fever, diphtheria, small-pox, and all diseases dangerous to public health, as well as to tyhoid fever, and that every case should be reported to the Health Officer, who is required to promptly attend to the restriction of the disease. The new law makes it a misdemeanor, punishable by fine or imprisonment, for the Health Officer to knowingly violate the enactment, or for any person to violate the orders of the Health Officer made in accordance with it. The actual penalty, however, which is incurred is—*Death!* And about one thousand people are lost in this State annually from typhoid fever alone. The saving of a large proportion of these lives is the real reason for the effort, in which it is hoped all people will join.

Treatment of Baldness.

Dr. E. Besnier, in the *Journal de Méd. de Paris*, states that the falling out of the hair may be checked and a new growth started by the following treatment: The hair should be cut short and a mild sinapism or rubefacient applied to the scalp; then every five days the following lotion is to be applied:

℞ Acid. acetic.,
Chloroformi . . . . . āā q. s. M.

The above should be used cautiously, as it is an irritant, and stimulates the hair powerfully. In connection with the above, the following pomade should be used:

℞ Acid. salicylic . . . . . gr. xv
Sulph. precip. . . . . ʒjss
Vaselini . . . . . ʒv.—M.

This pomade should be applied fresh every morning, the scalp having been previously washed. Fatty substances retard the growth of the hair and should not be used.—*Journal of Cutan. and Genito-urin. Diseases*, Oct., 1889.

Codeine.

Notwithstanding the large number of synthetical hypnotics now before the medical world, this old remedy has lately been again investigated and recommended by several authors in various diseases. Dr. Rheiner, of Berlin, speaks very highly of it, especially as a mild narcotic in cases of pthisis, where morphia is contra-indicated. Others also recommend it in certain diseases of women. —*Chemist and Druggist*, October 26, 1889.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

TUBERCULOSIS IN SLEEPING-CARS—A FALSE ALARM.

There is no more serious obstacle to real advance in the science or art of medicine than the unwarranted assertions sometimes made by men who occupy positions which give unusual weight to their utterances. It is unfortunate that such men do not seem always to appreciate the responsibility of their position, or to understand the limitations they should set to their *ex cathedrâ* statements. We are led to these reflections by the remarks made recently by Dr. J. T. Whittaker, of Cincinnati, before the Association of Railroad Surgeons, on "Tuberculosis in Sleeping-Cars;" in which he declared that it would be difficult to conceive of a conjunction of circumstances more directly contributive to disseminate tuberculosis than is offered in the palace car. The dangerous possibilities of the sleeping-car Dr. Whittaker compares to those of dogs confined in boxes and made to inhale atomized tuberculous material, who thereby become themselves tuberculous.

This, in our opinion, is a very dangerous example of false reasoning. It by no means follows because dogs become tuberculous when compelled to breathe tuberculous material, that men and women who travel in sleeping-cars are likely to become tuberculous because consumptives have occupied the same cars. There is not the least doubt concerning the possibility of infecting animals experimentally with tuberculosis; but they require conditions utterly different from those of a traveler who has consumptive companions, or predecessors. In experimental infection by inhalation it is indispensable that the sputum shall be either coughed or sprayed down the air passages of animals, or suspended thickly in a confined atmosphere which they are forced to respire; and it is well known that, with all these requirements rigidly met, the experiments frequently fail. How slight do the risks of infection in sleeping-cars appear in the light of these facts, and how absurd is it to intimate—as Dr. Whittaker does—that the exhalations of a single consumptive will contaminate the atmosphere of a sleeping-car for a considerable length of time!

As a matter of fact, the danger of acquiring phthisis in the manner suggested by Dr. Whittaker is not great, but exceedingly small. How small it must be will be appreciated by any one familiar with the most careful investigations in regard to the communicability of tuberculosis, and who remembers that such eminent investigators as Baumgarten, Bollinger, Celli, Guarnieri, who thoroughly believe in the tubercle bacillus as a cause of tuberculosis, deny infection through inhalation altogether.

In astonishing and regrettable contrast to this view, Dr. Whittaker's remarks might easily deceive one unfamiliar with the facts to believe that investigators are unanimous in

holding it to be easy to transmit tuberculosis to animals through inhalation. If this inference is not the one intended, Dr. Whittaker's opinions might be expected to rest upon some careful observations of his own, which demonstrate that the views of the best observers who have preceded him are erroneous. But, if he has made such observations, he certainly does not cite them. If there are any facts within his knowledge that support his alarming suggestions, they might be such as that he knew of cases of tuberculosis fairly attributable to infection in sleeping-cars—a tolerably easy sort of claim to make—or that he had gathered statistics showing that conductors, porters, and other sleeping-car employees, who are exposed to this danger almost all the time, are peculiarly liable to succumb to consumption. But Dr. Whittaker produces no evidence of this sort, and his utterances seem to be as unjustifiable as they are alarming. We regret to see them quoted in different directions and by influential medical journals without criticism, and hope that some of our contemporaries will join in in endeavoring to prevent the mischief which they are likely to do if allowed to pass unchallenged.

COMPULSORY NOTIFICATION OF DISEASE.

The Medical Society of the District of Columbia, in Washington, has been carefully studying the subject of the compulsory notification of diseases by physicians to the municipal authorities, and has just received a report from a committee appointed to consider the question of the adequacy of the present regulations for the prevention of diphtheria in that city.

The committee found that no physician or other person, in the District of Columbia, is required to notify the Health Officer of the existence of any contagious or infectious disease, except that of small-pox.

At the present time, the Health Officer has no power to make effective regulations. No notification is required to be made to the Health Officer, nor is any house placarded. The Health Officer could inspect school-houses when disease is known to be present, but he has no means of knowing this except by common rumor. The regulations for the government of the schools are made by a board of trustees. No physical examination of the scholars for admission to the schools is required, other than the production of a vaccination certificate. Teachers may send children home whenever it is found that contagious diseases exist in the family, or whenever a child has a fever or sore throat it is sent home. The committee thinks it would be practicable to require every scholar to produce a health certificate from the family physician, which health certificate should not only certify that the scholar had been vaccinated, but that he had not, within a period of thirty days, been exposed in his or her own domicile to the contagion of measles, scarlet fever, or diphtheria.

The committee suggests that the regulations in regard to small-pox should be made to include scarlet fever and diphtheria, and that the regulations governing warning signs, isolation, disinfection, and care of the sick-room, notice to the Board of Health, and interments, should be strictly enforced, with regard to these diseases, in the manner now provided in regard to small-pox. The committee proposes a law, making it the duty of every registered practicing physician in the District of Columbia to report, as soon as practicable, to the Health Officer, on forms to be furnished by that officer, the occurrence of any case of scarlet fever or diphtheria coming under his observation.

The proposed act also provides that it shall be the duty of the Health Officer to cause a suitable warning sign to be displayed from the front of the premises, where any case of scarlet fever or diphtheria is present, to cause the premises to be properly disinfected, and to issue instructions for isolation of the patient. It also makes it unlawful

for any person to visit or attend any public or private school, or place of public assemblage, or to appear on the public streets, or in the parks while affected with scarlet fever or diphtheria.

This report was discussed at great length and its ultimate fate is not yet determined. Such propositions usually encounter many obstacles in passing through large bodies of medical men, and others, even more formidable, when they come before legislators.

In the present case there is room to question the practicability and utility of certain provisions of the act proposed, although its purpose and general outline will be likely, we think, to meet with the approval of all students of public health.

NAPHTHOL IN THE TREATMENT OF TYPHOID FEVER IN CHILDREN.

The use of naphthol in typhoid fever has already been followed by considerable success in a large number of cases; the results obtained being attributable to the antiseptic properties of the drug. This treatment of typhoid fever was, according to the *Gazette Hebd. de Méd. et de Chir.*, Oct. 4, 1889, first introduced by Dr. Bouchard. Following in his footsteps, Dr. Legroux, of Paris, has adopted a similar therapy in the treatment of enteric fever in children.

The method advocated by him is as follows: As soon as the presence of the disease is confirmed, a purgative of calomel should be given. Two doses, of from five to nine grains, a few hours apart, are best. The administration of naphthol should be given two days later. This drug may be given either alone, or else in combination with salicylate of bismuth or salicylate of magnesia. If slight diarrhœa is present, three grains of beta-naphthol should be given every hour; and if the diarrhœa is copious, a prescription composed of thirty grains each or beta-naphthol and salicylate of bismuth, divided in ten powders, may be ordered. One powder may be given every hour, the whole ten to be taken within twenty-four hours. If there is any constipation, salicylate of magnesia may be substituted for the salicylate of bismuth in the above prescription, and a similar dose employed.

TENTH INTERNATIONAL MEDICAL CONGRESS.

The most recent German medical journals contain the Statutes and Programme of the Tenth International Medical Congress, which is to be opened in Berlin on August 10, 1890. It is evident that the Organizing Committee is doing all it can to insure the complete success of the coming Congress. The Congress will be divided into eighteen Sections, and each of these will be presided over by a Chairman and a number of honorary chairmen. On account of the various languages used, secretaries of various nationalities will be employed. The Committee on Organization will decide whether any paper presented shall be read in the general session or in its respective sections. This Committee also requests that any suggestions concerning the organization of the Congress should be sent to it before July 1, 1890.

Members taking part in the discussions will be requested to hand their remarks, in writing, to the Secretary at the close of session. The official languages of the Congress will be German, French, and English. Introductory addresses will be restricted to twenty minutes and individual remarks in discussions to ten minutes. Students of medicine and the laity, both male and female, will be admitted, on invitation of the Chairman, to the Sections in which they are especially interested.

—The number of students attending the Chicago medical schools this year is considerably increased. The average increase in the four regular medical colleges probably amounts to ten or fifteen per cent. over the previous year.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

THE STORY OF THE BACTERIA AND THEIR RELATIONS TO HEALTH AND DISEASE. By T. Mitchell Prudden, M. D. 16mo, pp. vi, 143. New York and London: G. P. Putnam's Sons, 1889.

So much is said about bacteria at the present time that a book written on the subject in the interest of laymen will find many readers. Dr. Prudden first explains that the human body is made up of cells in various combinations, and then shows how unicellular organisms are capable of all the essential functions of life, such as in the human body are performed by complex organs. The harmlessness of certain bacteria is strikingly stated in the following passage: "There is really very little difference, so far as wholesomeness is concerned, between the few thousand vegetable cells which we call bacteria, which may be clinging to the surface of a grape, and a few hundred vegetable cells of which the grape itself is composed."

Dr. Prudden has succeeded in presenting an admirable summary of what is known and believed regarding bacteria and bacterial diseases. The book is both interesting and instructive, and will be read with pleasure, especially by intelligent laymen.

TRANSACTIONS OF THE TWENTY-FOURTH ANNUAL SESSION OF THE HOMŒOPATHIC MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA, held at Philadelphia, September 18–20, 1888. 8vo, pp. 391. Philadelphia, 1889.

Among the papers in this volume is one on tinea tonsurans, by Dr. J. H. Classon, of Philadelphia. He gives a good description of the disease and reports five cases. He regards an ointment composed of one drachm of oleate of copper and four drachms of vaseline, as the most preferable local application. He is in error, however, when he states: "Observation tends to show that the growth of the trichophyton may produce tinea versicolor." The latter affection is caused by an entirely separate fungus—the microsporon furfur.

The largest paper in the volume is one on "Arsenicum Album," by the Farrington Club, of Pittsburgh. It is startling and somewhat amusing to read of the symptoms, which are alleged to be exhibited by a person taking the drug, attributed as personal characteristics to the drug. For example: "Arsenic is determined to commit suicide, he suffers so;" "arsenic causes great fear and anguish; sees ghosts day and night." Among the leading characteristics of arsenic are mentioned burning, and inflammation of the skin. According to the so-called law of similars, we should therefore expect arsenic to be useful in acute inflammatory skin affections. As a matter of fact it is useful in the dry, chronic scaly skin affections.

The book is well printed and well bound. It bears throughout distinct evidence that homœopathic practitioners are becoming more liberal.

ESSENTIALS OF PHYSIOLOGY, ARRANGED IN THE FORM OF QUESTIONS AND ANSWERS. Prepared especially for students of medicine. By H. A. Hare, B. Sc., M. D. (Univ. of Pa.), Demonstrator of Therapeutics in the Medical Department of the University of Pennsylvania, etc. Second edition, thoroughly revised and enlarged. 8vo, pp. iv, 173. Philadelphia: W. B. Saunders, 1889. Price, $1.00.

The author states, in the preface to the present edition, that he has endeavored to improve each portion of the work. The illustrations have been increased three-fold, and a greater number of questions and answers on the nervous system have been given, while others, which were not as clear as they might be, have been rendered easier of comprehension. The book in its present shape gives a good review of the essence of our knowledge of the blood, circulation, respiration, digestion, excretion, the nervous system, including the special senses, and of generation and the development of organs. It is calculated to be useful to students preparing for examination and to others who desire to refresh their memories by a few moments reading.

The last page of the book is numbered 193; but there are not that many pages in it, even if two advertising pages in the front, the title-page, and all the fly-leaves are counted.

MEDICINAL KALENDER FUER DEN PREUSSISCHEN STAAT AUF DAS JAHR 1890. Erste und Zweite Abtheilungen. Berlin: August Hirschwald, 1890.

The book which in Germany takes the place of the Pocket Records and Visiting Lists in this country, is a visiting list in one volume, and a general directory of the profession in Germany, with a vast deal of accessory information in another. It is of much interest to all who have an interest in German medical affairs, and an exceedingly useful guide to the location and work of men whose names occur in medical literature. It is a welcome visitor to our Editorial table and a good friend many times.

Literary Notes.

—J. B. Lippincott Company announces a new edition of *Remington's Practice of Pharmacy*, ready for delivery November 5. More than 200 pages and 140 new illustrations have been added, embracing over 100 autograph prescriptions on enamelled paper, and many other new features.

—Dr. Reichardt, who has for many years edited the *Archiv der Pharmacie*, has announced his intention of retiring. The journal will continue to appear under the joint editorship of Professors Schmidt and Beckurts, of Berlin.

Correspondence.

Treatment of Rattlesnake Bite.

To the Editor.

Sir: I see in the Reporter, No. 16, October 19, 1889, an article headed "Death from Rattlesnake Bite."

Why will the medical profession continue to play with these snake bites by the use of whiskey? Why not read such standard works on the subject as Cooper, Gibson and others? I know they are right in directing the use of olive oil. I have used it for forty years in a large practice of that class of cases, and in no case has it failed to give

immediate relief, and produce a permanent cure. Use none other than the pure virgin oil and it will cure every case, and no mistake. Yours truly,

C. R. Earley, M. D.

Ridgway, Pa.,
Nov. 12, 1889.

Gonorrhœa at Five Years of Age.—Death after Nitrous Oxide Anæsthesia.—Reunion of Cut-off Fingers.

To the Editor.

Sir: In the Reporter of October 19, a case of gonorrhœa in a boy five years old is reported by Dr. D. D. Custer, of Manayunk, Pa. In 1877 a woman brought her son, aged five years, to me, saying that something was wrong with him; that he cried when he urinated, and this was quite frequent. On examination I found he had a well-defined case of gonorrhœa. Investigation proved that the hired girl had seduced him, and he contracted gonorrhœa from her. My partner, at the time, was treating a young man who contracted the disease from the same woman.

In the Reporter of November 2, you mention a death from nitrous oxide gas, or rather from apoplexy following administration of the gas. Several years ago I administered nitrous oxide gas to a lady, for a dentist to extract some teeth, and she came near dying from what I then considered threatened apoplexy. The case you mentioned reminded me very forcibly of my experience then, and I hope never to have a repetition of it. In the same issue of the Reporter, Dr. A. Hamilton Deekens reports the union of a cut-off finger, which reminds me of what happened to an old physician many years ago; long before antiseptic surgery was practiced. A man, with a finger cut off, came to him, bringing the finger. The doctor was drunk, and sewed the finger back. It united nicely. But lo! the doctor had sewed it on with the palm surface turned the wrong way. The doctor, after sobering up, wanted to amputate the finger and try to put it back right, but the patient declined and the doctor was annoyed, many years, by having his mistake constantly exhibited as a great curiosity.

Yours truly,

S. W. Sanford, M.D.

Henning, Tenn.,
Nov. 5, 1889.

Notes and Comments.

Absence of the Uterus.

In the *Virginia Med. Journal*, October, 1889, Dr. Louis A. Bryan, M. D., of Houston, Texas, reports an interesting case of congenital defect. He was applied to by a mulatto woman and her husband for relief from an obstruction of the vagina which prevented perfect coition. After a preliminary examination, he appointed a day and invited Drs. Burroughs and Autry and Dr. Scott to visit the case with him and assist in an operation, if, after a careful examination, we thought it advisable to make one—his preliminary examination having only gone so far as to establish the existence and location of the obstruction.

At the time appointed it was found that the external organs were in normal condition and well developed. The index finger, being passed into the vagina, found it in a normal condition in all respects for about two-thirds of its length from the vulva; at this point it was perfectly closed by a membrane of the same character and equally dense and resistant as that of the walls of the vagina. With the index finger in the rectum and a sound passed into the bladder, the vagina could readily be traced to its terminal point, which was abrupt, and beyond which no tissue of any character could be detected between the finger and the sound except the walls of the bladder and vagina; as far as the examiners could explore there was no trace of a womb discovered. This, they decided, settled the question of an operation in regard to opening the vagina, and they did not proceed to the operation of dilating the sphincter ani and introducing the hand into the rectum to search for a womb, for it was thought that if such an organ was anywhere located, it had no connection with the vagina.

This subject was a bright mulatto woman rather above medium size, well developed, twenty-five years old, who had been married two years, had never menstruated, but suffered at each recurring period with severe pain in the head and a heavy sensation and some congestion of the eyes. When about seventeen years old she had to be relieved from the care of a child to which she was nurse for one or two days at each period on account of her severe suffering. She complained of no abdominal or other pains except those of the head.

She said that she had sexual desires and enjoyed sexual intercourse, at the conclusion of which there is a sense or feeling as if something were in the vagina which she has the desire but not the ability to discharge.

Directions for Using Plain Cod Liver Oil.

A few grains of salt on the tongue before taking, renders cod-liver oil palatable, and suggests sardines. A bite of pickle before and after, renders the dose acceptable. Where liquor may be safely used, a small quantity of good whiskey is one of the best vehicles for administering cod liver oil.

The dose should be small at first: say a half teaspoonful, gradually increased to a dessert, and even a table spoonful, three or four times a day, and is best taken a half hour after meals. In all cases it should be persisted in for some time, and without intermission.

The great point is to secure oil of undoubted purity and freshness.

Hyoscine as a Sedative.

Mr. A. S. Barling, in writing on the value of hyoscine as a sedative in *The Lancet*, October 26, 1889, says that in 1887 and 1888, when in residence at the Leeds Infirmary he frequently gave it, and its administration became quite the routine practice in almost all cases of mental derangement. The solution generally used has been one of the hydrobromate, one grain to 200 minims, or of the hydriodide. This was found to be more convenient than the weaker solutions which were tried at first. The usual dose to begin with was $\frac{1}{100}$ grain, but this was generally largely increased. He has given as much as $\frac{1}{30}$. Most of the cases that he has seen have been such as occur in the ordinary run of hospital practice—notably delirium tremens, acute mania following operation, and delirium caused by heart disease. In all of these its success has been most marked. The effect of the drug shows itself in from one to five minutes. The patient becomes less noisy, and his articulation indistinct, drowsiness then comes on, and, although in many cases the man seems to fight against the drug, he soon becomes quiet and lies quite still, often with his eyes partly closed. In about half the cases this state gives place to sleep. This is generally accompanied by stertorous breathing and by a peculiar twitching of all the voluntary muscles; the patient can, with great difficulty, be roused, and his pupils are dilated and do not react to light. Besides the cases mentioned above, Mr. Barling has given it to a man with intense neuralgia of the supra- and infra-orbital nerves. The patient was a confirmed opium taker, and morphia had little effect on him. Hyoscine frequently gained him some hours' sleep when morphia and chloral had failed. In yet another case, one of very severe chorea, it sent the patient to sleep after many drugs had been tried in vain. Unpleasant after effects following hyoscine are not so common as after morphia though there is often some dryness of the throat and weariness.

Source of Colors.

The cochineal insects furnish a great many colors. Among them are carmine, crimson, scarlet carmine, and purple lakes. A sea shell belonging to the purpura, and found in Japanese waters, gives a rich violet dye. The cuttlefish gives the sepia. It is the inky fluid which the fish discharges in order to render the water opaque when attacked. Indian yellow comes from the feces of the camel. Ivory chips produce ivory black and bone black. Prussian blue is made by fusing horses' hoofs and other refuse animal matter with impure potassium carbonate. Various lakes are derived from roots, barks, and gums. Lamp black is soot from certain resinous substances. Turkey red is made from the madder plant, which grows in Hindostan. The yellow sap of a tree of Siam produces gamboge; the natives catch the sap in cocoanut shells. Raw sienna is the natural earth from the neighborhood of Sienna, Italy. Raw umber is also an earth found near Umbria and burnt. India ink is made from burnt camphor and gum. The Chinese and Japanese are the only manufacturers of this ink. The process is a tedious one and requires great skill. The finer grades of India ink are delicately scented with attar of roses, and one stick about three inches long may cost four or five dollars. Age improves the ink. Mastic is made from the gum of the mastic tree, which grows in the Grecian Archipelago. Bistre is the soot of wood ashes. Very little real ultramarine is found in the market. It is obtained from the precious lapis-lazuli, and commands a

fabulous price. Chinese white is zinc, scarlet is iodide of mercury, and native vermilion is from the quicksilver ore called cinnabar.

Effect of Mental Impression.

A curious case of traumatic hysteria was recently reported by Dr. William C. Thompson. The patient, a man fifty years old, had seen an Italian killed by a shock from an electric wire. Two weeks later he was struck on the head by a cut wire; he at once grasped it in his hand and fell down, only recovering his senses several hours later after having been taken to a hospital. He was then found to have right hemiplegia and hemi-anesthesia and all the symptoms of typical hysteria. The wire that had struck was a "dead" one, that is, no current was passing through it at the time of the accident; the blow had also been but slight, causing no contusion.

Reception to Dr. Rihl.

Members of the Northern Medical Association and other professional friends tendered Dr. Henry W. Rihl a reception and banquet at the Colonnade Hotel, Tuesday evening, October 29. The special occasion of the banquet was the return of Dr. Rihl from a trip to Europe; but it was in honor of a career of forty years as a practitioner of medicine, and as a mark of the respect and esteem in which Dr. Rihl is held, both as a man and as a physician, by all who know him. The attendance was large and the occasion was a success in every way. Toasts were responded to by Drs. Rihl, Gibbs, Mills, Hess, Roberts, Collins and others. The toast master, Dr. E. W. Holmes, added much to the enjoyment of the evening by his geniality and wit.

Some Results of Compulsory Notification.

Dr. Campbell Munro, in recording the death-rate of the Jarrow urban district, in County Durham, England, during 1888 as 17.1 per 1,000—this being the smallest rate since 1871, when it was 34.7 per 1,000—takes occasion to refer to the operation in Jarrow of the compulsory notification of infectious diseases, and for this purpose he contrasts the period 1871–78 and 1879–88. In the former, when no such system was in force in the borough, the mean death-rate from all causes was 25.2 per 1,000; during the second period, when notification was in force, it was 20.8.—*The Lancet*, October 26, 1889.

Death from Chloroform.

A death from the inhalation of chloroform occurred at the Richmond Hospital, London, Oct. 12. The patient was a woman, who was about to undergo amputation of the thumb. She had taken a very few inspirations when her face was observed to become deeply congested. The administration of the anæsthetic was at once stopped, artificial respiration was set up, and the external jugular vein was opened, but she never rallied. At the autopsy examination the heart was found to be infiltrated with fat and the brain to be congested. The coroner's jury found that the anæsthetic was skilfully administered.—*British Medical Journal*, Oct. 12, 1889.

The Normal Thoracic Resonance in Left-handed Persons.

It is a well-known fact in clinical medicine that the normal percussion resonance of the thorax is higher pitched on the right side than on the left; Mr. W. H. Brazil, of Bolton-le-Moors, England, states, in the *British Medical Journal*, October 26, 1889, that so far as he has been able to ascertain, no mention has hitherto been made of an important exception to this rule which exists in the case of left-handed persons. In all the cases of this kind which he has up to the present time been able to collect the difference between the thoracic percussion resonance observed in them and in ordinary right-handed patients has been both uniform and decided. He sums up the results obtained on thoracic examination as follows: 1. The percussion resonance is higher pitched on the left side of the chest than on the right, this higher pitch affecting all regions of the thorax. 2. The vocal fremitus is greater on the right side than on the left, agreeing in this respect with the normal right-handed thorax. The first of these points has a certain degree of theoretical interest, inasmuch as it confirms the generally accepted explanation of the higher

pitch usually observed on the right side, namely that it is due to excess of muscular development on that side. It has also an obvious bearing on the diagnosis of an early stage of phthisis affecting the left lung, the points of distinction being: first, that the higher pitch in left-handed patients affects the entire left side of the chest instead of being confined to a particular region; secondly, that the vocal fremitus in the former case is greater on the right or lower pitched side.

Mr. Brazil mentions, in conclusion, that he is still collecting cases, and hopes shortly to publish a list with further particulars.

Human Spermatozoa.

Mr. E. M. Nelson in describing his observations on the human spermatozoa states that the head or spore has not been hitherto correctly figured. In all the drawings that he has seen the ovoid form having been delineated but with the larger end turned toward the tail, whereas the smaller end should be in that position. The head or spore fits into a cup, the outlines of which may be seen in both front and side views. This part does not appear to have been previously observed. At the bottom of the cup is an exceedingly variable part called the calyx, between which and the tail proper is the stem, and in the latter a structure that Mr. Nelson names the joint. On the spore he has observed a flagellum which he calls the filament, its purpose being to guide the spore into the micropyle, or the aperture into the ovum.—*The Microscope*, Oct., 1889.

What is Vaccinia?

In the October number of the *Archives of Surgery* Mr. Jonathan Hutchinson describes and analyzes in a masterly manner "three latent cases of gangrenous ulceration of the arm after vaccination." So closely did the symptoms simulate some of the manifestations of syphilis that several well-informed medical men held that they were cases of true syphilis. However, Mr. Hutchinson is of the opinion that they were probably cases of vaccinia. This strongly supports the view maintained by Dr. Creighton, that cow-pox is closely allied to the great pox. It should be clearly understood that Dr. Creighton never suggested their identity, but only their similarity. He says: "A careful and unbiased survey of the facts has convinced me that cow-pox sores must be credited with a power of producing secondary symptoms (I say nothing of tertiary), not because they have the contamination of venereal pox in them, but because their nature is the same, or parallel with, that of the venereal pox itself."

The important question arises and is asked by Mr. H. H. Taylor in *The British Med. Journal*, Oct. 26, 1889, What is vaccinia? Is it cow-pox, or horse-pox, or horse-grease cow-pox, or horse-pox cow-pox, or small-pox cow-pox? Jenner, in his "masterpiece of medical induction," asserted it to be that form of udder disease inoculated from the greasy heels of a horse through the medium of the milker's hands. Sir John Simon maintains that it is small-pox cow-pox. Mr. Hutchinson holds this view. We read: "If we suppose that cow-pox was a disease communicated to the cow by the hands of a milker suffering from variola," etc. It is quite necessary to suppose this, as there is not a single authentic case on record in which a milker with variolous pustules on his hands has been known to infect a cow.

On November 17, 1881, an outbreak of cow-pox was reported at La Forêt, in Eysines. It was a so-called "spontaneous" attack, and not small-pox cow-pox. The Medical Officer to the Local Government Board solicited and obtained some of the lymph, and started the Vaccine Establishment at Lamp's Conduit Street. So Dr. Buchanan believes vaccinia to be the dairyman's cow-pox, or pap-pox. It comes to this, then, that we have at least three varieties of lymph circulating in this country, each believed to be the "life-preserving fluid" by eminent authorities — namely, horse-grease cow-pox (Jenner), small-pox cow-pox (Simon and Hutchinson), cow-pox or pap-pox (Buchanan).

One problem the Royal Commission on Vaccination has to solve is, What is vaccinia? If they settle this one point only, their time will not be altogether wasted.

Castor Oil Chocolate.

An interesting item which is going the rounds of the pharmaceutical journals, suggests the palatable administration of castor oil by incorporating it with cacoa. For this purpose finely powdered cacoa, deprived of

oil, such as is found in commerce, is used. This is incorporated with the castor oil and a sufficient quantity of vanilla to flavor it is added. Next sugar is added, and the whole ground upon a heated slab. Finally the mass is transferred into moulds, and allowed to become cold.

The following proportions may be used:

Cacoa, free from oil and powdered	50 parts.
Sugar, in powder	100 "
Castor Oil	50 "
Vanilla, in powder	q.s.

The size of the moulds may be such as to require from three to six of the "chocolate drops" to form a dose for an infant.

Treatment of Pigment Spots, or Chloasma, in Pregnant Women.

Dr. M. V. Moreier, in the *Monatsheft für prakt. Dermatologie*, recommends the following salve for the treatment of the pigmented spots, or chloasma, not unfrequently observed in pregnant women:

℞ Cocoa butter . . . . } each 2½ ounces.
Castor oil . . . . . }
Oxide of zinc . . . . . 4½ grains.
White precipitate . . . 2 grains.
Oil of roses . . . . q. s.
Dir. Apply morning and evening.

—*Le Bulletin Médical*, October 2, 1889.

Antiseptic Ventilation.

A novel apparatus for filtering and regulating the temperature of air, and, if desired, of sterilizing it, was brought forward at the Worcester meeting of the Sanitary Institute, of England, by Mr. S. M. Burroughs. This apparatus, by means of a revolving fan, blows air to all parts of the building, the temperature being raised in winter by means of waste steam, and cooled in summer by substituting cold water for the steam. The air passes through a coarse strainer to remove dust and floating particles and, when required, is impregnated with the vapor of carbolic acid, eucalyptol, pinol, etc., by means of a suitable mechanism. It is, of course, only applicable in buildings such as factories, where motive power is obtainable; but where that is provided, it is certainly an effectual and economical method of obtaining forced ventilation.—*Medical Press and Circular*, Oct. 9, 1889.

Kehrer's Operation for Depressed Nipple.

In the REPORTER, June 15, 1889, we reproduced from the *Annals of Surgery* an account of an operation for depressed nipple successfully planned and executed by Dr. Oxford, of Chicago. Another method of accomplishing the same purpose is that known as Kehrer's, which is described and figured in a communication to the *Lancet*, July 6, 1889, by Mr. G. Ernest Hermann, Obstetric Physician to the London Hospital.

The cases in which this operation is indicated are those in which the nipple lies in a sort of cup, so that it does not project enough above the surface for the child to seize it, but is otherwise well formed. The operation consists in the excision of a ring of skin, or of two crescentic pieces of skin, surrounding the nipple; so that in the healing of the denuded surface the approximation of the internal and external edges of the ring or crescent may so pull upon the skin immediately surrounding the nipple, and forming the cup in which it lies, as to obliterate this cup and render the nipple accessible to the child.

Mr. Hermann states that he has performed the operation twice. One of the cases he has lost sight of, but in the other he is able to judge of the effect of the operation. The patient, thirty years old, has had three children. The first child she suckled with the left breast, the nipple of which was well-shaped and prominent, but not with the right. The right nipple was sunk in a hollow, so that the child could not seize it, and its apex was drawn in so as to form a dimple. In May, 1887, she was delivered of her second child in the General Lying-in Hospital. She suckled, as before, with the left breast, but the child was unable to take the right. Five days after delivery Mr. Hermann performed Kehrer's operation on the right breast. As the dimple on the nipple ran horizontally, he removed two crescent-shaped pieces of skin, one above the other below the nipple, each piece measuring about two inches long by about an inch across its widest part. The patient returned to the hospital to be delivered of her third child in May, 1889. She can now suckle with both breasts. The right nipple, although not so prominent or well-shaped as the left, yet projects enough for the child to grasp it. The object of the operation has therefore been attained.

NEWS.

—Dr. J. Frederick Herbert has removed to 1313 Arch Street, Philadelphia.

—Dr. Robert W. Reid has been appointed Professor of Anatomy in the University of Aberdeen, in place of Professor Struthers, resigned.

—The Metaphysical College of Massachusetts has ceased to exist. It dissolved, as recorded by resolutions of its corporators, on October 29, 1889.

—The Department of State has received a despatch from E. H. Plumacher, United States Consul at Maracaibo, denying most strongly the reports of yellow fever in Venezuela.

—A medical student, of New York, is reported to have manifested his lunacy by the strange freak of eating a portion of the body of a negro which was being dissected.

—On Nov. 12 the American Association for the Study and Cure of Inebriety, gave a banquet to Dr. Joseph Parrish, at Burlington, N. J., in honor of his seventy-first birthday.

—A number of London physicians have organized a "Hypnotic Society," for the purpose of studying hypnotic phenomena, and securing a law prohibiting public séances of hypnotism, mesmerism, etc.

—The new Christ Hospital in Jersey City, New Jersey, was dedicated November 13, by the Rev. Bishop Starkey, of the Newark diocese, assisted by Bishop Quintard, of Tennessee, and a number of local clergymen.

—The Rosemont, Pa., druggist who was convicted at the October term of court at Norristown, of selling liquor without a license and without a prescription, was sentenced, November 11, to pay $500 fine and to undergo three months' imprisonment.

—Dr. William A. Hammond, of Washington, D. C., is conducting a number of experiments in the treatment of epilepsy by localizing the brain lesion, trephining and paring the convolutions. He will publish the result of his experiments in the near future.

—Dr. Robert Duncan, surgeon of the Pacific Mail Steamship *Colon*, has brought suit against the city of Brooklyn for $60,000 damages, on the ground that he had intermittent fever, and the Brooklyn health authorities, acting on the belief that he had yellow fever, had him removed to quarantine.

—The trustees of the Salem, Mass., Hospital have decided to employ a resident physician, and to make the superintendency a non-professional office. This will drop the present superintendent, Dr. George Z. Goodell. It is understood that the position of resident physician will be tendered to Dr. J. P. Fessenden.

—The Board of Health of Detroit has endorsed the crematory from a sanitary point of view, but is somewhat chary about recommending the process for other cases than death from small-pox. A law exists there, which declares that bodies of persons who have died from small-pox cannot be removed for re-burial unless they have been previously incinerated.

—The latest use to which the phonograph has been put is the recording of discussions. Quite recently a paper to be presented at the First District Dental Society of New York State, was privately read and discussed before some Philadelphia dentists in this city, over a phonograph. The cylinders were sent to New York, and the discussion repeated after the reading of the paper.

—The grand amphitheatre of the Paris Faculty of Medicine took fire, October 7, during a meeting of the French Congress of Surgery and damage to about $14,000 was caused. Three immense pictures by Matout were destroyed, one of them representing Ambroise Paré applying a ligature for the first time, valued at $2,000. The bust of Hippocrates, gazed upon by so many generations of students, was also destroyed.

—Dr. Frank S. Billings, lately in charge of the patho-biological laboratory of the State University of Nebraska, has removed to Chicago, Ill., to resume the study of the non-recurrent diseases of children—scarlet-fever, mumps, measles, and whooping-cough. Dr. Billings has fitted up a laboratory in which he proposes to prepare virus for the inoculation of swine against hog cholera, and to continue the study of that subject.

—By the will of the late John Crerar, which was admitted to probate in Chicago November 14, 1889, personal property valued at $3,500,000 and real estate valued at $50,000, was disposed of. To his friends and relations he makes bequests aggregating $1,300,000, and the rest is given to a number of charities, and to erect a colossal statue of Abraham Lincoln. About $1,500,000 is set apart for the erection and maintenance of a public library in Chicago, to be known as the "John Crerar Library."

W. R. WARNER & CO'S

NEW AND RELIABLE RECIPES FOR PHYSICIANS PRESCRIBING.

In order to get the full therapeutic effects, physicians will please specify (WARNER & CO.) when ordering or prescribing.

☞The coating of the following pill will dissolve in 4½ minutes.☜

PIL: CHALYBEATE COMP.

(WARNER & CO.)

Nux Vomica is added as an ingredient to Pill Chalybeate to increase the tonic effect when desired.
Composition of each Pill.—℞ (Chalybeate Mass.), Carb. Protoxide of Iron, gr. 2½., Ext. Nuc. Vom. gr. 1-6.
DOSE—1 to 3 Pills.
Most advantageously employed in the treatment of Anæmia, Chlorosis, Phthisis, Scrofula, Loss of Appetite, etc.

PIL: ANTISEPTIC.

Each Pill contains: Sulphite Soda, 1 gr. Salicylic Acid, 1 gr. Ext. Nuc. Vomica, ¼ gr.
DOSE—1 to 3 Pills.
Pil. Antiseptic is prescribed with great advantage in cases of Dyspepsia attended with acid stomach and enfeebled digestion following excessive indulgence in eating or drinking. It is used with advantage in Rheumatism.

Prepared by WM. R. WARNER & CO.

PIL: ANTISEPTIC COMP.

(WARNER & CO.)

Each Pill contains: Sulphite Soda, 1 gr. Salicylic Acid. 1 gr. Ext. Nuc. Vomica, ⅛ gr. Powd. Capsicum, 1-10 gr. Conc'l Pepsin, 1 gr.
DOSE—1 to 3 Pills.
Pil. Antiseptic Comp. are prescribed with great advantage in cases of Dyspepsia, Indigestion, and Malassimilation of Food.
Supplied upon physician's prescription by all leading druggists.
1228 MARKET ST., Phila. 18 LIBERTY ST., New York.

EVERY PHYSICIAN

prescribing Cod Liver Oil (and who does not?) wants to know that his patients get the best that can be obtained. This is effectually secured by specifying "**BAKER'S**" whose firm (established in 1830) have given the greatest attention to the improvement and perfection of this all important remedy. In the various conditions in which Oleum Morrhuæ is indicated the Practitioner must decide the best form of administration. To meet such conditions we offer:

BAKER'S COD LIVER OIL.

BAKER'S EMULSION WITH HYPOPHOSPHITES OF LIME AND SODA.

Baker's C. L. Oil with Ext. of Malt.

Baker's C. L. Oil, Lime and Wild Cherry.

Above goods are accessible through the wholesale trade to all Retailers, and may be prescribed with the utmost confidence as to Purity and Excellence.

JOHN C. BAKER & CO., PHILADELPHIA, PA.

Physicians and Students of Medicine

are invited to attend the meeting of the

THERAPEUTICAL SECTION

OF THE

POLYCLINIC MEDICAL SOCIETY

AND THE

Lectures on Practical Subjects

by members of the Faculty, delivered under the auspices of the Society,

——On Tuesday Evenings——

throughout the Winter Course, at the College Building,

N. W. Cor. Broad and Lombard Sts.

For announcement of full course of instruction, for physicians only, apply to

L. W. STEINBACH, Secretary.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders**, is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds**, handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe, and healthful Home.

PNEUMONIA.—IMPACTED RENAL CALCULUS.—THE "TACHES BLEUATRES" OF TYPHOID FEVER.[1]

BY J. M. DA COSTA, M. D.,

PROFESSOR OF THE THEORY AND PRACTICE OF MEDICINE IN JEFFERSON MEDICAL COLLEGE, VISITING PHYSICIAN TO THE PENNSYLVANIA HOSPITAL, ETC., ETC.

Gentlemen: The first case to which I shall call your attention this morning is this man, whose present attack began last Monday. After working all day, during which time he was much exposed to the weather, he had a severe chill followed by a fever. This, however, did not prevent his going to work the next morning, but he was troubled with a feeling of great heat, and a pain in the lower part of his right leg and foot. He also complained of a pain in the right side of his chest which was aggravated by coughing and talking. He had no diarrhœa and no epistaxis. On admission to the hospital, he was found to be a large, well-nourished man. His temperature was 101.4°, pulse 90, full and strong, conjunctivæ of a yellowish tinge, skin dark, abdomen scaphoid. Forced inspiration developed considerable pain in the right side of the chest, and there was some dulness near the right nipple, as well as posteriorly, accompanied with marked tenderness. Splenic dulness was increased. The auscultatory signs were blowing respiration and cough. His temperature soon rose after admission to 105.8. He slept poorly, and complained of great shortness of breath. The tubular breathing extended to the apex. In other words he had a spreading pneumonia of the right side. He was given five grains of carbonate of ammonia, and ten drops of digitalis every four hours, and a poultice was applied to his right side.

[1] Delivered at the Pennsylvania Hospital.

There is no doubt as to the diagnosis. The tubular breathing and dulness, the yellow countenance, the pain and difficult respiration all indicate the presence of pneumonia. His sputum was muco-purulent, tenacious, but not rusty-colored. Now I have told you of the early fever history of the case, but I want to call your attention to a drop in the temperature that took place on the third of the month. From a temperature of 103.5° on the evening of the second it dropped the next morning to 98°, and from this on, with one single exception on the evening of the fifth, when we have a temperature of 101.4°, it has ranged about normal, or, in fact, slightly subnormal. Coincident with this extraordinary drop of temperature there has taken place a gradual diminution of the signs of consolidation of the right lung, but it is evident that the temperature had fallen before this change in the lung had commenced. His temperature this morning is only 97°. We have, then, here a case, where a cure has taken place in pneumonia though the physical signs as yet do not indicate complete resolution. The yellowness of the skin has largely disappeared. This morning we find no longer any bronchial breathing; it is gone. There are some sub-crepitant rales on inspiration, with prolonged expiration. Around the right nipple there is still a faint bronchial sound, and some dulness, as you notice; that is, at this point the consolidation has not yielded. The man is practically convalescent. His pulse for the last few days has been only 58 to 60. Under these circumstances we will suspend the administration of digitalis. He is now taking five grains of carbonate of ammonia every third hour. Considering that all febrile phenomena have passed away we might with advantage stop this and place him upon the iodide of ammonia, five grains every third hour. There is a little cough still remaining, so we shall add to this two drops of the deoderized tincture of opium, enough to allay the irritation. His expectoration is still muco-purulent. We shall increase his diet and give him a little meat. The sixteen grains of quinine which he is taking at present we will cut down to eight. His urine has contained no bile during the febrile state, but there was a trace of albumin which has now disappeared. There has been no special examination made for the chlorides.

There are two points in this case that impress me, and may interest you. These are, first, the diffused pains, the pains in the extremities being marked; and secondly, the absence of rusty-colored sputum; and thirdly, the termination of the case by crisis. I will consider these points separately.

Firstly, the man was seized with a chill, followed by pain in the chest and pain in the lower extremities. Diffused pain in pneumonia is very common. I have known cases where the pain was referred entirely to the region of the ileo-cæcal valve, and I have known instances where it was entirely in the extremities, as in this case. I do not want you to be deceived by such cases and have your attention led away from the chest. These pains are often misleading.

Secondly, this man has had no rusty-colored sputum. This only proves that this symptom is not a necessary accompaniment of pneumonia. Otherwise there is nothing of importance attached to the fact.

The third point is the termination of the disease by rapid dropping of the temperature, that is, by crisis. Very frequently on a certain day, between the seventh and the ninth generally, we have a rapid drop of temperature, while the physical signs show that complete resolution has not taken place. If after this fall it rises again, the case is not doing well and the prognosis is grave. The history of this case is a little uncertain as to dates, and I do not know what day this drop occurred, but it was about a week after the chill, so it comes within the range I have laid down.

I will next show you a case with the following history: There is nothing of special note in his past history. He has always been healthy up to the present attack. There is no venereal history. In July last he commenced to pass bloody urine. This was accompanied at first with no pain, but in about a week's time he complained of a dull, aching pain in the lumbar region, followed shortly by excruciating pain in the right kidney and radiating down the right ureter. This lasted twenty-four hours. His urine then cleared up. A severe chill preceded this attack. Eight weeks ago he had another attack of pain with bloody urine, and the urine has remained bloody since. He suffers from headache. He urinates freely every two hours with no pain, nor is the flow ever checked. He has passed several clots. He has some cough and expectoration, but no diarrhœa. His temperature was 99.2°, pulse

75, respiration 17. His tongue was large, pale, and œdematous on admission upon the fifth of November. The examination of the heart and lungs was negative. His abdomen was markedly tender over the course of the right ureter and there was tenderness over the right kidney. His urine was a dirty red color and contained some granular and bloody casts, some albumin and a large increase in the phosphates. No stone was discovered in an examination of his bladder.

This morning he has pain in the right side along the course of the right ureter and over the right kidney. There is tenderness on pressure. He has a little pain on the left side and over the left ureter, but not so severe as that over the right side. I cannot find any swelling or tumor upon either side. Then there is no increased dulness in front. The liver dulness is normal; the splenic dulness extends just to the margin of the ribs. The patient's tongue is flabby, marked with the teeth, and slightly coated. His pulse is compressible. The heart sounds are normal. Upon questioning him I learn that his pain is a steady one. He has never had more than the two attacks and has never passed any calculi. His first attack came on after heavy working in the harvest field. He has never had chills and fever; and this is an important point.

Now what is this case? There are two or three possibilities. It may be a bleeding from the bladder, but this is most unlikely. Healthy people do not bleed from the bladder except there be a local cause, as stone. This can here be set aside. If there should be the least evidence of scurvy or purpura, we might account for the blood as coming from the bladder; but these do not exist. The kidneys must therefore be the seat of the hemorrhages, and the large amount of albumin and the presence of bloody and granular casts proves that the man has hematuria of a renal origin. Now what does this mean? When we have a case of bloody urine, the cause of which we have clearly traced to the kidney, our first duty is to exclude scurvy and purpura, which we have done. Another point at once then arises, and especially in laboring men, and that is the possibility of the hematuria being due to malaria. This condition often gives rise to bloody urine, particularly at this time of the year. But this man has shown no malarial symptoms whatever, and the fact that he has had only two attacks of hematuria, with an interval of several weeks between them, excludes this factor. The same conclusion may be reached with regard to the presence of the parasites, which at times produce bloody urine. There is nothing of that kind here.

There are still two propositions to be considered. The case may be one of cancer of the kidney, for bleeding occurs in cancer at irregular intervals; or it may be due to an impacted stone. I think it is the latter. The long interval between the attacks of pain is against the diagnosis of cancer, in which case the pain would be more constant. Then the man is not emaciated sufficiently to confirm the presence of cancer. So, reaching the diagnosis by what we call the method of exclusion, we have come to the conclusion that this man has an impacted calculus of the kidney. If this be correct, which kidney is affected? He has pain on both sides. More than one distinguished surgeon has cut down upon the wrong kidney. Often culculus of the kidney will set up a pain upon the opposite side, through sympathy, which may be worse than the primary pain. But as this man has complained of severe pain in the right side and along the course of the right ureter, I think the stone is in the right kidney. We will keep the man in bed and watch the urine for a fragment of the stone, which I think is probably phosphatic from the history.

Now as regards the treatment, we will consider the medical treatment first. A phosphatic stone requires rest in bed, a diet of the mildest kind, comprising broths, a large amount of milk, farinaceous foods, a liberal supply of drinks, not alkaline, such as plain water, weak lemonade, flaxseed tea, and ginger tea. In addition to this, we will give him dilute muriatic acid, twenty drops three times a day, and every morning and evening a pill containing $\frac{1}{12}$ grain of the extract of belladonna with oil of juniper. We give the acid to dissolve the stone if possible, and to render the urine less alkaline. We give him belladonna to favor the passage of the little fragments broken off. Patients who suffer much from calculi are apt to know this, and keep a supply of belladonna on hand. The juniper is a diuretic, and also has a happy influence upon people who have calculi in the kidney. One of the principal ingredients of many patent medicines for this condition is juniper. The surgical aspect of the case we will leave for discussion until after we see how he gets along under medical treatment.

The next case is a man who has just been admitted. He is an Italian and gives no history. That he has typhoid fever we know. He has diarrhœa and had a temperature of 105° last night. He was sponged with tepid water and alcohol under a blanket. This reduced the temperature one degree in an hour, and was repeated twice, the temperature falling to 101.4°. We could not have had better results from phenacetin or any antipyretic. But I show him to you to show a very rare eruption in typhoid fever, the blue spots or "taches bleuâtres" of the French. These are coarse and larger than the red spots of typhoid fever. They are modified distinctly by pressure but do not disappear. They exist on the abdomen, but more particularly upon the lower part of the left chest. Now I do not know that they are of any very great importance beyond their occurrence, but they are never seen in light cases. They bespeak an alteration in the character of the blood. They have not the regular type of the red spots. The patient's temperature this morning is 101$\frac{2}{5}$. He had two stools during the night. He is taking half an ounce of whiskey every second hour, quinine four grains morning and evening, twenty drops of dilute muriatic acid every third hour. This is a case for free acid treatment, just on account of the condition of his blood. We shall continue the sponging as needed. He is on a milk diet, four ounces of milk every second hour, day and night, forty-eight ounces in the twenty-four hours. In addition to this we will give him a pint of beef broth.

Massage in Rickets.—Dr. Silfverskiöld speaks very favorably of massage in the treatment of rachitis. He begins with the lower extremities, using considerable pressure in a direction from below upward, and making energetic passive movements of the ankle, knee, and hip-joints. He then passes to the abdomen, thorax, neck, and upper extremities, exciting increased respiratory movements by making pressure on the chest. Each séance lasts for from ten to fifteen minutes, and the treatment is continued through a period of from four to six weeks. At the beginning, the patient usually complains of pain during the manipulations, but this soon passes away. The author claims to have obtained excellent results in a number of cases.

Communications.

FLAP-SPLITTING IN PERINEORRHAPHY, WITH SPECIAL REFERENCE TO TAIT'S OPERATION.[1]

BY X. O. WERDER, M. D.,

PITTSBURGH, PA.

The perineum has always been a very fertile field for the surgeon. Numerous operations have been devised for restoring this structure to its normal anatomical condition. Nearly all of these operations have had this in common, that they started out by removing the old cicatricial tissue, and very often also healthy tissue, causing really a new defect for the purpose of covering an old one. With the progress of plastic surgery, by the formation of flaps in other regions of the body, surgeons commenced to transfer this method of operating to the perineum. Diffenbach, I think, was the first to suggest the covering of the defect by flaps. He says:

"In those cases where there is a considerable loss of substance, the transplantation of an adjoining piece of integument may be resorted to—*i. e.*, a plastic operation may be attempted." (Marcy: The Perineum.)

To Langenbeck, however, belongs the credit of having originated and practiced splitting the recto-vaginal septum, forming two flaps—one anterior and one posterior—and utilizing them for the purpose of making a new perineum. This method is described by Verhaeghe and Biefel (Hegar and Kaltenbach: *Cyclopædia of Obstetrics and Gynecology*) as follows:

"*Langenbeck's Perineosynthesis.* — Two fingers of the left hand in the rectum stretch the parts transversely, and a narrow strip of the entire thickness of the vaginal wall is then removed with curved scissors. A flap, rounded below, is cut in the posterior vaginal wall and dissected, in an upward direction, from its base, the recto-vaginal septum being thus divided into two lamellæ. The posterior lamella remains *in situ* and serves to close the rectum; the anterior lamella is drawn forward and united to the anterior portion of the new perineum, where it is to

[1] Read before the meeting of American Association of Obstetricians and Gynecologists in Cincinnati, Sept., 1889.

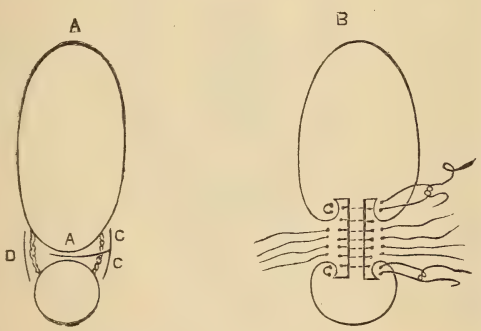
form a surface running obliquely downward. A quadrilateral space is described upon the inner surface of each lip by means of a scalpel, and is freshened by dissecting a layer of tissue about a line in thickness. Anteriorly, the incision begins where the posterior commissure of the vagina ought to be; posteriorly, it passes into the denuded septum on both sides. The entire denuded surface is about one and one-half inches long by three-fourths of an inch wide.

"The sutures toward the rectum are first introduced, then the flaps of the vaginal wall on both sides are united to the anterior part of the new perineum by two or three sutures. Finally, the fissure in the perineum is united from before backward."

Though this operation is now obsolete, it being complicated, somewhat difficult to understand from a mere description, and probably not as successful in its results as the modern ones, it was certainly a great advance over the methods of operating at that time—about forty years ago. It certainly does great credit to its originator, as the principle of it was correct and is now underlying all the flap operations of the present day.

The modification of Langenbeck's perineosynthesis by Wilms, Bischoff, and Staude, do not materially differ from the old operation, except that they are simpler in their technique and based on more scientific principles; but as they are, like Langenbeck's, not pure flap operations, I will not go into their details.

Fig. 1.



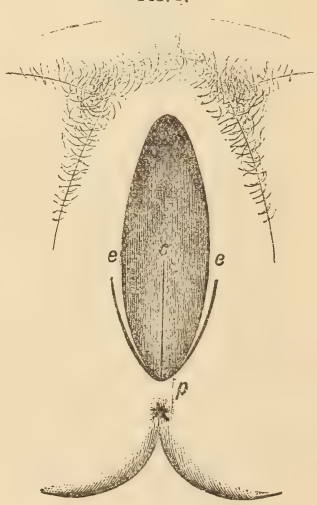
Method of Voss, taken from Sänger.

Voss's Method.—To Voss, of Christiania, belongs the credit, according to Sänger, of having first devised and performed a pure flap operation—that is, an operation in which no tissue is removed, but in which the defect is closed by the formation of flaps. He performed his first perineorrhaphy in 1865, and described his method, illustrating it by two plain but good diagrams, in the *Transactions of the Medical Society of Christiania*, of the year 1870. (Sänger: *Centralblatt für Gynäkologie*, No. 47, 1888.)

In complete lacerations, he separates the rectum and vagina to a depth of about one-fourth of an inch (Fig. 1, *a*), then a semicircular incision is made on each side of the septum recto-vaginale between skin and cicatricial tissue (*b*, cc). A straight knife is now introduced and carried beneath the whole cicatrix until its point appears at the first incision (*a*), then cutting through the whole septum until you have two distinct flaps—anterior and posterior—the anterior flap forming the vagina, and the posterior the rectum. The vaginal flaps are sutured from above, the rectal flaps from the rectal surface, and the intermediate raw surface is united by perineal sutures, as seen in the diagram.

This method, which is really the prototype of all the modern flap operations, does not seem to have been very successful; for, of the four cases reported by Voss himself and his follower Nicolaysen, two of them were succeeded by recto-vaginal fistula.

Fig. 2.

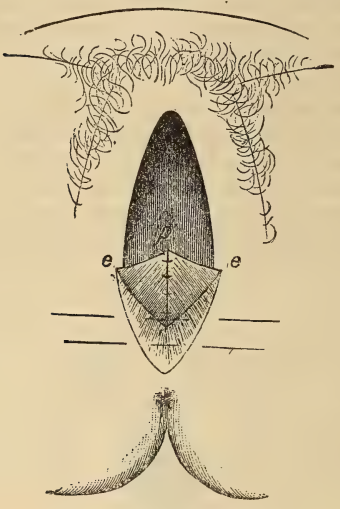


Simpson's method.
Incomplete rupture of perineum.

Much simpler in technique and followed by better results is the method of Simpson, of Edinburgh, the first record of which is found in Hart and Barbour's work on Gynecology, first edition, published in 1882. The authors give to John Duncan, of Edinburgh, the credit of originating it.

Simpson's Method.—In incomplete ruptures an incision is made in the median line of the columna rugarum at the point *c* (Fig. 2), carried down to the ruptured perineum, p, then two lateral incisions are made, starting at point p, to the inner surface of the labium minus on each side (Fig. 2, *ee*). The two triangular flaps thus formed are now dissected free and turned up (Fig. 3), so that the points (*p*) will form the new commissure of the vagina; they are then united by silk or wire sutures, which are tied on the vaginal surface of the flaps. Two or three perineal sutures are then passed to close the cavity left between vagina and rectum. (See Fig. 3.)

Fig. 3.

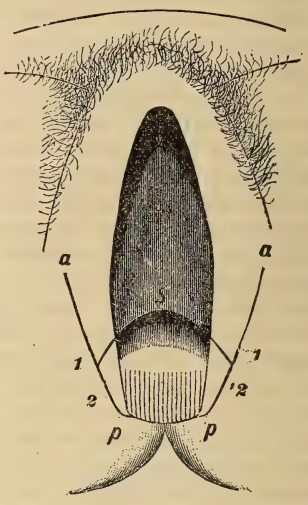


Simpson's method.
Incomplete rupture of perineum.

(Taken from Hart and Barbour.)

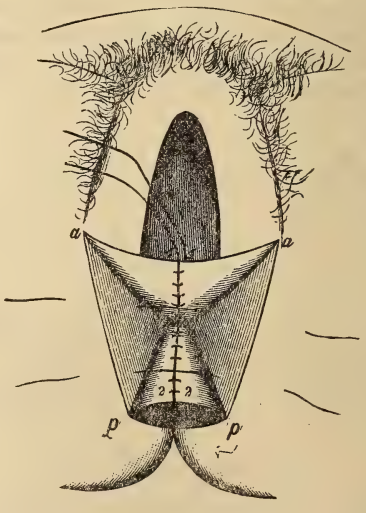
In complete ruptures the recto-vaginal septum is divided by an incision at point *S* (Fig. 4), carrying it outward to point *1*; then another incision is made from point *a*, at the lower edge of the labium minus, parallel to the labium majus, meeting the other incision at point *1*, and continuing to *p*, at the end of the torn sphincters. The same is repeated on the other side. After dissecting off the flaps thus outlined by three incisions, we have formed four different flaps—two vaginal (Fig. 4, *a 1 S* and *a 1 S*), and two rectal (Fig. 4, *S 1 2 p* and *S 1 2 p*). The vaginal flaps are turned up toward the vagina so that the points *1 1* meet and form the posterior commissure of the new vagina, as in Fig. 5, and united as in previous operation, by silk or wire sutures knotted on the vaginal surface of the flaps, and the sutures are left long so as to protrude from the vagina. The rectal flaps are now turned

Fig. 4.



back into the rectum so that points 2 2 meet, as in Fig. 5, and united the same way as the vaginal flaps knotting the sutures in the rectum, but choosing catgut preferably for suturing material. The sutures are cut

Fig. 5.



Operation for complete lacerations of the perineum.

short. We have now finished the repair of vagina and rectum; it remains, however, to close the raw, open surface between rectum and vagina by deep external silver-wire sutures, as in the incomplete operation above

described. The perineal sutures are not knotted, but tightened by button plates. The edges of the skin are united by a few superficial sutures.

This operation is not only very popular in some parts of England, but has found advocates among some of the most prominent gynecologists of the Continent, especially in Germany, by whom it is preferred to all other operations, and particularly so for cases of prolapsus uteri, as it is said to form a very firm recto-vaginal septum. In ten out of eleven cases of complete procidentia reported by Sonntag,[1] he obtained excellent results, in the eleventh case a small portion of the perineum healed by granulation. Zweifel and Hegar also recommend this operation for prolapse cases.

In 1887, H. Fritsch described, in the *Centralblatt für Gynäkologie*, vol. ii, page 473, a method of operation for complete ruptures of the perineum, which has given excellent results and which presents many advantages over other operations.

Fritsch's Operation.—After separating the rectum from the vagina, by an incision through the recto-vaginal septum about one and five-tenths centimeters deep, until both organs are freely movable independently of each other, he frees the stumps of the sphincter ani muscle on both sides, and then, passing a ligature through each one temporarily, he pulls them down, restoring thereby the natural condition of the rectum. The everted rectal mucous membrane is by this means generally turned into the lumen of the bowel, so that the freshened surfaces of the flaps come in contact with each other. When the vaginal flaps are also drawn up we notice two distinct rents in the flaps, the upper, or vaginal, being considerably longer than the lower, or rectal. The rectum is closed by interrupted catgut sutures which are inserted from above—*i.e.*, on its vaginal surface, care being taken not to puncture the rectal mucuous membrane. The knots become buried in the wound; this is done in order to prevent the passing of fecal matter or flatus into the wound. When the ends of the sphincter muscles, through which the temporary silk ligatures have been passed, are reached, the ligature is removed and replaced by a catgut suture. The vaginal flaps are also united by catgut sutures. The remaining perineal wound is closed by two or three deep sutures introduced from the perineal surface, as in Simpson's operation.

The principal difference between the last two operations is, that in the latter the cutting is strictly confined to the recto-vaginal septum; it only requiring one incision, which is more or less transverse, and that the rectal sutures are passed from the vaginal sides of the rectal flaps. Of the two, Fritsch's operation is, therefore, the simplest in technique, and its results seem to be all that can be desired.

Marcy's Operation.—The operation devised by one of our fellows, Dr. Marcy, which he first described at the meeting of the American Medical Association in 1883, is also based upon the principle of flap-splitting.

"The sphincter having been stretched and the bowel thoroughly emptied, two fingers in the rectum, the posterior third of the vagina is separated, with knife or scissors, from its vulvar attachments. The recto-vaginal space is easily found without much loss of blood, and the dissection of the vagina from the rectum is carried into the lateral sulci as far as may be judged sufficient. The separated flap is lifted and held by an assistant; then I introduce a large curved needle, the eye near the point, armed with tendon, deeply from side to side; the opposite end is threaded, and the needle withdrawn, carrying the tendon with it. The suturing is continued in this way, until the required number of stitches are taken. . . . Usually, four or five stitches are required to unite the posterior vaginal fascia, and then the separated ends of the perineal muscles are included in the deep sutures. Any other needle and stitch may be used, but I prefer the one above mentioned.

"If the ends of the retracted perineal muscles seem tense when united, I use the lateral supports, applying one or two pins, as heretofore described. These serve simply to retain at rest the coapted parts, and lie parallel to the anus outside the sutures. If the operation is aseptic, the after-treatment is simply rest in bed, and the cure is complete."

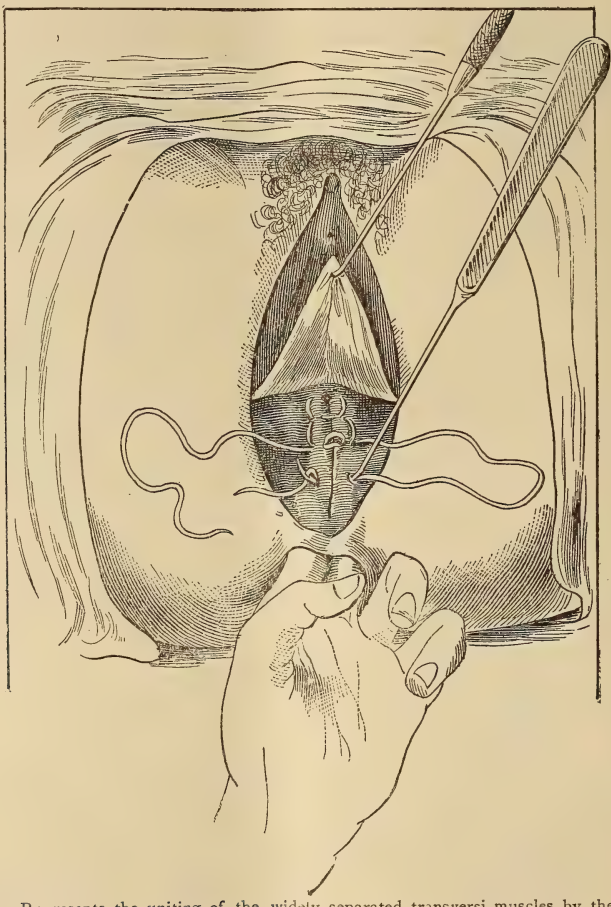
The peculiarity of Marcy's operation, therefore, is not so much his method of preparing the flap, as is his method of suturing, which is by buried catgut or kangaroo tendon, supported externally at the perineum by his double pins, when found necessary. It is

[1] Sonntag, in Verhandlungen des III. Congresses der Deutschen Gesellschaft für Gynäkologie, Freiburg, June, 1889; Centralblatt für Gynäkologie, page 500.

a method equally simple and successful, because based on sound anatomical principles. For a further description of the operation, I refer to Dr. Marcy's excellent paper on "The Perineum," read before the Association of Obstetricians and Gynecologists at its first annual meeting.[1]

The operations of Voss, Simpson, and Fritsch, and, to some extent, also that of Marcy, all have this in common, viz., that the sutures are introduced from three different sides for the closure of the raw surface made—namely, from vagina, rectum, and perineum—and in this they do not differ from the old triangular operation. This, however, is much simplified by Tait's new perineal operation first described by Sänger in Volkmann's *Sammlung klinischer Vorträge*, 1887. (Ueber Perineorrhaphie durch Spaltung des Septum recto-vaginale und Lappenbildung.) In this operation only one kind of sutures is employed—namely, perineal sutures—both in incomplete as well as in complete lacerations. Lawson Tait first described his method of perineorrhaphy by flap-splitting in the *Transactions of the Obstetrical Society of London*, vol. xx, page 291, 1879. Since then he has repeatedly modified his operation, so that his newest method hardly resembles the one first described by him. According to Meinert,[1] there are no less than four different modifications of the operation made by himself. They are, however, all based on the one principle—namely, to restore the perineum to its former anatomical relations by splitting the old cicatrix, but without removing

FIG. 8.



Represents the uniting of the widely separated transversi muscles by the double continuous, buried, animal suture. The posterior vaginal wall is lifted and held by an assistant.

[1] See Transactions of the American Association of Obstetricians and Gynecologists, vol. i, page 69, 1888.

[1] Centralblatt für Gynäkologie, vol. xii, page 649.

any tissue. The older operations have been known and practiced in this country for some time, but the new and latest operation seems comparatively unknown—at least the only references I could find to it are in the *American System of Gynecology*, by Howard A. Kelly, and by Hadra, in his book *Lesions of the Vagina and Pelvic Floor*, and they both took their descriptions from Sänger's pamphlet. Paul F. Mundé is the first American to describe the operation minutely, and based on his personal experience of seventeen cases, in the *American Journal of Obstetrics*, July, 1889, illustrating it by excellent woodcuts and plates. In Europe, especially in Germany, this new method has attracted considerable attention since Sänger's publication and has found many advocates among the best authorities, as Zweifel, Martin, and Winiwater. Induced by these publications and the high recommendation it received from such reliable sources, I tried it for the first time about eight months ago, the case being a complete rupture of the perineum. The result was so highly satisfactory that I have since operated on every case presenting itself to me by Tait's new method.

[TO BE CONCLUDED.]

BRAIN ABSCESS OPENING INTO NASO-PHARYNX; WITH RECOVERY.[1]

BY L. B. GILLETTE, M. D.,
OMAHA, NEB.

As the results of the case I am about to report is so unusual, I hope you will forgive its imperfections. I do not know that I have ever heard, or read, of a case of brain abscess recovering without surgical interference. Possibly you have; possibly you have seen them. If so, I can assure you that they are one of the rarest surprises of a doctor's life. We frequently make a favorable prognosis and get badly disappointed; but in such cases, when you are compelled to make the worst possible prognosis, how delighted you feel that your patient is getting well in spite of you and your endeavors. I possibly may be wrong in my diagnosis, although I am supported in it by two other physicians. But I think you will be convinced by the history of the case, and its terrible results.

Dr. Nancrede, of Philadelphia, says: "Various cases have been reported in which the pus from cerebral abscesses has found its way, by ulceration through the bones, into the nasal fossæ or ear, recovery having ensued. The amount of pus and the suddenness of its discharge have been the arguments chiefly relied upon to prove the cerebral origin of these abscesses, when recovery has taken place. I have no doubt myself, that some of these have been really cases of circumscribed intra-meningeal accumulations, although in a few, *post-mortem* examination has demonstrated their cerebral origin."

Last October a lady called at my office, wanting some medicine for her son, saying that he had malarial fever. On inquiry I found that she had got her diagnosis from a charlatan across the way, who had been treating the young man for several days. I had not asked many questions before I became satisfied that the case demanded personal attention. The next morning (October 26) I called, and you may well imagine my surprise when I found a case of inflammation of the brain staring me in the face. The following is the history as it was given to me:

"G. A., aged 20 years, farmer by occupation, above the average size and weight, strong and healthy. During the early part of September he was working on an embankment with a wheel-scraper. While driving along with it loaded, it, in some way, became unlatched and the handle, in flying up, struck him forcibly under the chin, knocking him down a sixteen-foot embankment, where he lay unconscious for twenty or thirty minutes. After regaining consciousness he remained around in a dazed condition for an hour or so, then went to work again, thinking he was all right. About a week afterwards, for several days he noticed that something was wrong with his eyes, and said that he could not look at anything steady. Sometimes he would look at a bird flying and it would look as if it were two birds, and that it would wobble around; on looking at a post in the ground, for instance, it would not keep still, but would dance up and down and sideways. He especially noticed this peculiar condition with the right eye, and moreover, could not see as well out of it as with the left. About

[1] Read by title at the Seventh Annual Meeting of the American Rhinological Association, Chicago, October 10, 1889.

the 15th of October he went to work in a brickyard, worked there three days, and complained of being nervous and of having a slight headache. On the evening of the third day he got soaking wet in a rain, went home cold, and had a chill, followed by fever. His mother gave him a purgative and quinine. He was better the next day. The following day he had another chill, followed by high fever, when they decided to call a doctor, who, as I said before, pronounced it malarial fever. On my advent into the case, I found the young man suffering with intense headache all over the head, the pain extending down between the shoulder blades, and particularly into the right arm. Both pupils were widely dilated. He had the room darkened, as he said the light hurt his eyes. On opening the door I noticed no response of the right pupil to light. The left one only slightly. His temperature was 101°; his pulse 105. He was very irritable. I readily recognized that I had an inflammatory condition to deal with, and made up my mind it was the result of his injury six weeks before.

The next day I brought with me to see the case another physician, not to hold a consultation, but that he might see it, as it was such an interesting case.

Since the recovery of the patient I have been provoked many times to think that I was so careless as not to take each day minute details of it for future reference, but it is so well impressed upon my mind that I can give you all the important points. To my surprise the inflammation did not get worse, nor did the young man die within thirty-six hours, as I had predicted, as well as the other doctor. But there gradually developed within the next three days the most marked case of compression of the brain I ever saw. His temperature went down to 96°; his pulse as low as 42; his respirations to 9 or 10; and there was complete paralysis of the right side, partial of left, and complete loss of sensibility, with complete loss of consciousness. He gradually became indifferent to light and finally lost the sense of sight and the sense of hearing. He remained in this condition three or four days without any perceptible change.

Why did I not operate? I will tell you. I was satisfied that the abscess was so deep within the brain substance that he would surely die if I did, and I felt sure he would die if I did not; and, as the family thought he was sure to die anyway, they relieved me very much by saying that they did not want their boy cut up by a lot of doctors. Fortunately, for him, the act of swallowing was not interfered with, and by placing nourishing and concentrated food in his mouth, he would swallow it, and he got his food and medicine regularly. Imagine my surprise one morning on finding my patient much improved. The mother told me that during the night he had a violent attack of coughing and showed me what he spit up. It was about an ounce of green, stinking pus, with mucus. From that time he began to improve. There was immediately a return of consciousness, a quickening of the heart's action and respirations. I examined his throat and found that the pus came from above. I examined the Eustachian orifices and saw that no pus came out of them, but that it came from above still farther, and that on leaning forward it would come out of the anterior nares. The discharge lasted two weeks. Where it came from exactly, or how it got through, I never could tell. My opinion is in favor of the ethmoidal and sphenoidal sinuses. As a result of my patient's terrible ordeal, he was when I saw him three months ago, totally blind in both eyes, the sense of hearing was lost in the right ear, he has no use of his right arm, and his mind is not what it was. Could he have these results without some destruction of the brain tissue proper? Could he have the same results from an intra-meningeal accumulation?

You probably want to know my treatment. I can assure you I did not do much. At first I used the regular antiphlogistics, such as opium, mercury, quinine, cold applications to head and cupping the back of the neck, and the triple bromides as they were indicated. But as soon as I had well marked compression, I began using eighty grains of iodide of potash each day, and kept it up for thirty days. In fact, I began with the iodides the second time I saw him.

Do not waste Alcohol.—The alcohol used in washing microscopical sections, and in many other operations, should not be thrown away, but placed in a bottle labeled "old alcohol," and used in the alcohol lamp, for washing balsam off of slides, for hardening animal specimens, and for numerous other purposes which will suggest themselves.

LAPAROTOMY FOR INTESTINAL OBSTRUCTION.[1]

BY CORNELIUS KOLLOCK, A. M., M. D.,
CHERAW, S. C.

Intestinal obstruction, once regarded as one of the great bugbears of the profession, may be now said to be shorn of much of its terrors, and to rank with hitherto insurmountable difficulties that are every day being relieved by laparotomy. The danger of opening the peritoneal cavity, and thereby producing fatal peritonitis, has been a cherished dogma taught in the medical schools of all countries. It is not a little singular that medical men should so long have been wedded to this belief, whose experience should teach him that the peritoneum is as little liable to take on inflammatory action as any other tissue of the body, if not less liable, and that when it does become inflamed, this inflammation is always symptomatic, and depends on some pre-existing cause. Chomel, than whom there can be no more reliable authority in pathology, said more than forty years ago that he had never seen a case of idiopathic peritonitis. While few in modern times have been so bold as to dare gainsay the opinion of this learned pathologist, yet many have been slow to adopt the idea, and still more slow to act upon it. Even after the intrepid McDowell came to the front, and, impelled by his robust moral courage, opened the peritoneal cavity with the view of removing cysts, there were those in the profession, both in this country and in Europe, who were more disposed to condemn the operation than to extol McDowell for his brilliant surgical exploit. While this proved that the peritoneum can be divided with impunity, there was still many a "doubting Thomas." Some of them were of strength and prominence in the profession, who could not divest their minds of the old idea that a wound of the peritoneum was necessarily fatal. McDowell's success gave quite an impulse to abdominal surgery, and many who had previously stood aloof came forward as advocates of laparotomy. But it had to move slowly and cautiously. Both in America and Europe it was condemned. The celebrated Dieffenbach said, as late as 1848, that "any man who would open the peritoneal cavity was no better than a murderer, and should be placed in the criminal dock and tried for his life." But in time a change came over the spirit of the dream of even the Nestor of Continental surgery, and Dieffenbach's views as regards abdominal surgery were so modified that a short time before his death he expressed the opinion that ovariotomy might be justified where there was good assurance that the cyst had not formed adhesions with the adjacent tissues. If he had lived longer it is probable that he would have been a successful ovariotomist and a strenuous advocate of laparotomy.

While the history of ovariotomy for the past twenty or thirty years has established the fact that the peritoneal cavity can be entered with safety, and admitting that it can be divided without serious consequences for the removal of a neoplasm, there still exists with many a hesitancy and dread in resorting to it for the relief of intestinal obstruction. But the cautious and patient researches, and the brilliant results of operations of Leichenstern, Bulteau, Rafinesque and Peyrot on the Continent, and those of H. O. Thomas and Frederic Treves, of England, and R. H. Fitz, of our country, have, in the minds of all thinking men, established laparotomy for intestinal obstruction as an authorized and legitimate surgical procedure. The time, we trust, is near at hand when no intelligent surgeon will hesitate to open the peritoneal cavity for the relief of intestinal obstruction when assured of the mechanical nature of the obstruction, and of the strength of the patient to stand an operation of as much severity.

A brief report of two cases that came into my hands recently will illustrate not only the necessity of a resort to laparotomy in all such cases, but the importance of the operation being done as early as practicable. To dally with the case day after day till the patient's strength is exhausted, and a high grade of peritonitis has set in, is to throw away precious time, and to rob the patient of nearly all chances of recovery.

Case 1.—A stout, healthy lad, 18 years old, was seized on the night of August 12, 1888, with a violent pain near the umbilicus. A physician was called, and various remedies were used, such as sinapisms to the abdomen, enemas and large doses of opium, but with no relief. I first saw the case at 6 P. M., on

[1] Abstract of a paper read before the Southern Surgical and Gynecological Association, November 13, 1889—with an additional case.

August 13, twenty hours after the attack. He was almost in a state of collapse, bathed in a cold, clammy perspiration, and the pulse quick and feeble. Stercoraceous vomit had occurred twice. The enemas brought away nothing except what lay below the point of strangulation. The abdomen was greatly distended, and tympanitic. Feeling assured that there was internal strangulation of the bowel, I at once determined to resort to laparotomy. An incision of three inches was made in the linea alba, below the umbilicus. As soon as the peritoneum was opened, a coil of intestine, heavily congested, of a purplish color, made its appearance. Just at this point the strangulation was found. A diverticulum about three inches in length, and attached at its extremity by a shred of fibrous tissue to the mesentery where it joins the gut, formed, with the ileum, from which it sprang, a loop, through which the coil of intestine had slipped and become strangulated. The portion of intestine confined was released by simply dividing the fibrous band and setting free the end of the diverticulum. This afforded immediate relief from pain, and in a short time there were one or more movements of the bowels, and large quantities of offensive gas and fecal matter were discharged. This patient made a quick recovery, and has enjoyed uninterrupted health since the operation. A delay of a few hours would have proved fatal in this case. The bowels above the strangulation were highly congested, and of a dark purple color. The patient's strength was failing rapidly from the violence of pain, excessive vomiting, and the want of nourishment.

Case 2.—A young man, 25 years old, whose general health had always been good until sometime during the month of November, when he had violent attacks of what was called bilious colic—a very unmeaning term, which should be expunged from medical nomenclature. The pain was in the lower portion of the region of the liver and around the umbilicus. Several times during the latter part of November and during the month of December, a number of gallstones were passed, varying in size from that of the head of a pin to that of a pea. This was, of course, accompanied by violent pain, such as was experienced in previous attacks. On the night of January 2, 1889, there was another attack, more violent and distressing than any of a previous date. The physician called, supposed it was a similar attack to those of former occasions, and resorted to the treatment that had previously afforded relief. The pain, though to some extent paroxysmal, was very intense all the time, notwithstanding that morphia was administered in half grain doses every hour or two for more than twelve consecutive hours. Immense doses of purgative material were administered, in the shape of castor oil, Epsom salts, olive oil, rhubarb, and calomel, with no benefit, but doubtless with more or less injury. In the afternoon of January 4, about forty hours after the attack, stercoraceous vomit came on and the patient got rid, through the mouth, of large quantities of fecal matter, fluid, and offensive gas. This afforded more relief than all the anodyne, and the patient was able to take some milk and a little chicken broth, with apparent relish. But in the course of a few hours vomiting returned, and the milk and chicken broth were thrown up in a crude and undigested state, along with more stercoraceous matter. This condition of affairs continued until 5 o'clock on the morning of January 7, 1889, nearly five days after the commencement of the attack. It was then I first saw the case. There was no doubt in my mind, nor was there any doubt in the mind of the attending physician, as to the nature of the trouble. The whole abdominal region was greatly distended, from the ensiform cartilage to the pubis, and there was much tenderness. Pulse 140 and weak, temperature 104°. In this emergency, what was to be done? To leave the patient as he was, was simply to turn him over to death. Laparotomy, severe and dangerous under far more favorable circumstances, was the only procedure that offered any hope. This could not promise more than one chance in fifty, in the condition the patient was then in. The consent of the family was readily obtained, and the patient was anxious for the operation. At 6 A. M., on January 7, 1889, I opened the peritoneal cavity by an incision of three inches in the linea alba, about one inch below the umbilicus, and search was made for the cause of the obstruction. The colon had become twisted on itself, and a knuckle of bowel had slipped through a slit or aperture in the omentum; and in addition a roll or band of omentum was pressing firmly upon it. The band of omentum was divided, the bowel drawn out and untwisted. This removed the cause of obstruction, and there was soon an audible explosion of offen-

sive gas, followed in a short time by a discharge of fecal matter.

This operation was in itself a success, and the patient may be said "to have died cured," for the obstruction was removed and all pain had entirely disappeared. Death took place thirty hours after the operation, from exhaustion.

What would have been the chances of this unfortunate young man, had the operation been performed earlier, is a question difficult of solution. Being young, with good habits and good health, it is my opinion that if the operation had been done three days earlier, about the time of the first appearance of stercoraceous vomit, he would stood as good a chance for recovery as any one who undergoes the operation of laparotomy.

Case 3.—A strong, vigorous man, 44 years old, of good general health, with the exception of occasional attacks of indigestion, consequent upon torpor of the liver, was seized October 11, 1889, with violent pain in the bowels. I saw him on the 13th, about forty-three hours after the attack. His abdomen was much distended, tender, and tympanitic, and stercoraceous vomit had occurred twice at intervals of two hours. The cavity was at once opened by an incision of four inches. The abdominal walls were very thick from a superabundance of adipose tissue, which somewhat embarrassed the operation and made the incision longer than would have otherwise been necessary. As soon as peritoneum was divided a mass of intestines much distended and highly congested protruded. The obstruction was found in the ilio-cæcal region—was an intussusception or invagination of the bowel. It had evidently not existed very long, as no adhesions had been formed. It was easily reduced by drawing out the invaginated portion. After the obstruction was removed, there was no effort at defecation. This was evidently due to a partial paralysis of the bowel, caused by overdistention, impairing the contractile power necessary to establish peristatic action. By the use of the aspirator the gas and fluid were removed from the intestine, and then by pressing gently with my hand along the track of the intestine the fecal mass was started, which soon made its exit through the rectum. This operation was entirely successful, and a good recovery is the result. It is now more than three weeks since the attack and the patient is in all respects very comfortable.

A FORMULA FOR ASTHMA.

BY J. B. JOHNSON, M. D.,
WASHINGTON, D.C.

The causes of spasmodic asthma may be either direct or indirect; and when the disease occurs during the middle period of life, it is usually of a persistent form and is accompanied more or less frequently by bronchitis and emphysema. It is said that asthmatics very rarely die during a seizure; but in almost every instance death results from one of the complications of asthma, viz., bronchitis or emphysema. Both the direct and indirect causes of an attack are numerous, and although the asthmatic may be taught to avoid many of them, yet they are so abundant and varied, that it is almost impossible for him to conduct himself so prudently as to escape them all.

Attacks of spasmodic asthma may often be controlled by dry-cupping, morphine and many antispasmodics. The greatest chance of relieving the disease depends upon the influence which can be exerted upon the bronchitis and emphysema. For this purpose I have found nothing equal to the following:

℞ Syrupi hypophosphitum comp. . . f℥ jss
Syrupi acidi hydriodici . . . . . f℥ vj
Extr. euphorbiæ piluliferæ fluid. . . f℥ vj
Extr. nucis vomicæ fluid. . . . . f℥ j
Syrupi simplicis . . . . . f℥ j
Aquæ destil. . . . . f℥ ij

M. et Sig. A tablespoonful every three hours. Shake well.

This mixture is usually tolerated well by the stomach, and I have seen both the bronchitis and the emphysema to yield under its influence, while the interval between the attacks of asthma have become very much lengthened.

PROGRESS OF CREMATION.—There are now thirty-nine crematories in various parts of the world. Italy has twenty-three, America has ten, while England, Germany, France, Switzerland, Denmark, and Sweden have one apiece. In Italy there were two cremations in 1876; the number rose to fifteen in 1877, and in 1888 the number was 226. Since 1876, 1,177 cremations have taken place in Italy, while the combined numbers from all other countries brings the total only to 1,269.

Foreign Correspondence.

LETTER FROM BERN.

Carbolic Acid in Snake-bite.—Snake-bites in Switzerland.—Typhoid Angina.—Cocaine as a Substitute for Chloroform or Ether in Herniotomy.

Bern, October 15, 1889.

Carbolic acid seems to possess a considerable antidotal power against the poison of snake-bites, or at least against viper poison. Some months ago, Dr. Miniat, of Clarens-Montreux, Canton Vaud, published the report of the case of a boy, aged 12, who, while working in a vineyard, had had his right forefinger bitten by a viper (*vipera s. pelias berus*, Germ. *Kreuz atter*), measuring about 55 centim. in length. When seen by the author immediately afterwards, the boy was deadly pale and weak, fainted repeatedly, and vomited incessantly. Two small, dark fang-punctures were found on the tip of the finger, and the whole hand and forearm was intensely tender and swollen. Dr. Miniat at once injected several syringefuls of a 3 per cent. carbolic solution, both into the wound and along the swollen limbs, after which he wrapped up the latter in carbolized cotton, applied a bandage with a slight pressure, and administered several drops of liquor ammoniæ acetatis with water internally. The results of the treatment surpassed all expectations: all the symptoms of poisoning rapidly vanished; on the third day the boy was seen working in his father's vineyard, as if nothing had happened.

Quite recently, Dr. Frei, of Spluegen, Canton Grisons, has reported another similar case. A strong, healthy boy, 10 years old, while engaged in picking some berries on a mountain, was suddenly attacked by a large-sized viper (*v. berus*) which drove its fangs into the palmar aspect of his right forearm, three fingers' breadth above the wrist. Six hours later the patient was brought to Dr. Frei in a state of an extreme collapse, with his whole right upper limb enormously swollen, hard, cold and extremely tender to the slightest touch. Following Dr. Miniat's plan, Dr. Frei injected hypodermically three syringefuls of the carbolic solution (one into the bites, another just below the elbow-joint, and the third above it), applied cotton dressing, and gave the patient a glassful of strong Veltlin wine. Shortly afterwards the boy fell into a quiet sleep of ten hours' duration and awoke in the best of spirits. In fact the only symptoms that remained were some swelling and tenderness on pressure, which disappeared in a day or two, yielding their place to a temporary greenish-yellow discoloration of the forearm. Pointing to his and Miniat's cases, Dr. Frei recommends a trial of carbolic acid injections as an initiatory treatment in all cases of snake-bite.

Snake-bites, by the way, are apparently a very rare occurrence in Switzerland. In the *Correspondenz-Blatt für Schweizer-Aerzte*, 1888, No. 19, p. 592, Professor C. Kaufmann, of Zurich, says that personally he has met with only two cases of the kind, in both of which the patients were bitten on a finger by the *vipera berus* and both resulted in recovery. In one of the patients, an adult man, the treatment consisted in painting the wound with the tincture of iodine, and the application of an antiseptic dressing; in the other, a boy 12 years old, in enlarging the wounds and thoroughly treating them with a 50 per cent. solution of carbolic acid. After instituting a special inquiry, Dr. Kaufmann could collect the history of only four other cases which had occurred during the decennium of 1877–1886. One was communicated by Dr. Bugnion and referred to a boy 7½ years old, bitten on the forefinger by a *vipera aspis;* he was treated, 24 hours later, by the wound being painted with tincture of iodine and the use of diaphoretics; recovery ensued in about ten days. Another case was reported by Professor Socin, of Basle; a woman, 56 years old, was bitten on her little finger by a snake of the same species; under a treatment consisting of the internal administration of liquor ammoniæ and the local application of ice and cold lotions, she recovered in about six days. The remaining two cases, communicated by two practitioners of Canton Aargau, were those of a woman, aged 34, and a young man, both bitten on the hand by the *vipera berus* and treated one by the local use of liquor ammoniæ, the other by unknown means; both making a speedy recovery. The *vipera berus* and *v. aspis* are the only poisonous snakes infesting our happy "land of health-resorts."

Dr. A. Vonwiller, house physician to the Cantonal Hospital in St. Gall, furnishes an able contribution to our as yet but scanty knowledge of a peculiar ulcerous angina occurring in the course of enteric fever. The faucial affection was first accurately described

by Nonat in 1843, later on the history of some cases was published by Comby and Duguet, G. Wagner, Schott, Cahn, and Landgraf. All but one of these observers believe that this complication of typhoid fever is very rare; Cahn alone asserts that a careful repeated examination of the patient's throat would discover the angina in a far greater number of cases than is usually credited. Dr. Vonwiller's experience seems to support Cahn's statement; at least, during the last three years he came across seven cases of the kind. According to his observations, the affection is peculiar to enteric fever and mostly occurs in severe cases. As a rule, it makes its appearance during the second week of the primary disease and lasts from a few days to a fortnight and disappears spontaneously, without any special treatment. By itself the angina does not in the least aggravate the patient's state. Still, being liable to occur mainly in grave cases, the symptom is of considerable prognostic value. The affection is characterized by a rapid development of single or multiple, sharply defined, circular or ovoid shallow ulcers situated on the soft palate or faucial pillars, and varying in size from $\frac{1}{12}$ to $\frac{1}{4}$ of an inch in diameter (or from the size of a pin's head to that of a lentil). Their floor is lined with a scanty coat of a gray-reddish, gray-white, or yellowish color, any marked peripheral tumefaction or infiltration being absent, and the congestion but slight. The erosions are not accompanied either by swelling of cervical lymphatic glands or by painful swallowing, and hence may be easily overlooked. They heal from the periphery towards the centre, without leaving any visible scar. Sometimes they are accompanied, followed or preceded by identical ulcers on the labial mucous membrane. No typhoid bacilli could be discovered in the erosions in any of the cases yet examined. The pathology of typhoid angina still remains entirely obscure.

Some time ago, Professor Roux, of Lausanne, published a short, but very instructive and suggestive paper on cocaine as a surgical anæsthetic, in which he said, among other things, that he was successfully employing the alkaloid in all cases of herniotomy, injecting under the skin (along the line of the incision) a few syringefuls of 1 per cent. solution of the drug. There scarcely can be any doubt that in every ordinary case of operation for strangulated hernia choloroform or ether can be most conveniently substituted by the cocaine. Nevertheless the local anæsthetic is still reported to be but rarely used, and is neglected even by country practitioners, who are often compelled to operate without any assistance worthy of the name, and presumably must experience all the inconveniences which attend general anæsthesia far more acutely than hospital or town surgeons do. Appealing mainly to such country practitioners and pointing to the said inconveniences, Dr. Veniamin D. Sheffer, of Riazan (Russia), emphatically recommends an extensive trial of cocaine in herniotomy. For the sake of illustration, he adduces two cases of incarcerated ruptures (one of an aged woman with an umbilical hernia, the other of a male peasant, 32 years old, with an inguinal one) in which the operation lasting about an hour was performed absolutely without pain from the beginning to the end (including the insertion of sutures) by a preceding injection of one or two grains of the alkaloid, dissolved in 2 drachms of a 4 per cent. boracic acid solution. In both of the cases the wound rapidly healed *per primam.*

New York Correspondence.

Delinquents in the County Medical Society.—Hygiene in Public Schools.—Prize Essays.

The Medical Society of the County of New York has a membership of over nine hundred, and a number of these fail to pay their dues. Depriving them of the right to vote or to hold office has not forced them to pay up, and it is impracticable to sue them at law. The society therefore on Oct. 28, Resolved, That hereafter members two years or more in arrears of dues shall have their names omitted from the published list of the society, and that while thus in arrears such members shall receive no notice of the society's meetings nor any of the society's publications.

The society publishes a catalogue of the physicians of New York, including in one list the names of its members and in another the names of all other physicians who have registered in the County Clerk's Office. Members of the county society receive this catalogue free, which is nearly of the value of the annual dues, three dollars. It is believed that the adoption of this resolution, which is about the mildest way in which the society could proceed to stir up its derelict

members, will result in bringing a good many of the delinquents around to the Treasurer's office. The legality of the measure, however, was questioned by one of the members.

The society has a good deal of business to transact during the course of the year. Its Board of Censors and counsel have got illegal practitioners pretty well under control. The greatest transgressors who, it would seem, cannot be reached through the courts are the advertisers of quack medicines. We read in the papers of the families of some of these taking a high position in social circles because of the wealth which the people have seen fit to bestow upon them in return for their being humbugged.

Dr. Van Santvoord, for the Committee on Hygiene, reported the result of an investigation of the sanitary condition of the schools in the city. Five years ago the Committee made an investigation, and found that certain serious defects existed; the schools were crowded, as many as seventy-five pupils were all assigned to a class in the primary departments, the number of square feet of floor space for each pupil was only five, and of cubic feet air space seventy. In the new buildings these defects had been to a very considerable extent corrected, yet there was overcrowding in some districts, while in others the population had much decreased. In the parochial and Sunday-schools, and in some of the private schools, the sanitary regulations were less observed than in the public schools. Yet there were few instances where children with contagious diseases were permitted to attend. The exceptions were mostly in cases of contagious ophthalmia. Injurious consequences had sometimes resulted from teachers and principals trying to secure a large percentage of attendance. The report recommended not less than two hundred cubic feet air space to each scholar, nor less than thirty square feet floor space.

The physicians of New York seem to be remarkably ethical, only two complaints had been presented to the Committee on Ethics, in one of which the parties complained against were found not to be members, while in the other the complaint was dismissed for want of sufficient cause.

The impecunious medical man who hopes to bridge over a cold day by a prize awarded for an essay is apt to meet with disappointment. But one essay had been offered in competition for the prize of the county society, and that was deemed unworthy, inasmuch as it did not fulfill the conditions requisite in regard to originality. Dr. Douglas thought the conditions on which the prize was to be awarded might well be altered, for in twelve years only one essay offered in competition had been successful. Dr. Corning thought the prize should be awarded for the best paper read before the society during the year. The Comitia Minora was instructed to consider this matter and report back.

PERISCOPE.

Arthritic Hemoptysis.

In the *Lancet*, Oct. 26, 1889, Sir Andrew Clark has an article on the non-tubercular and non-cardiac hemoptysis of elderly persons, in which he says:

It is not my intention upon this occasion to enter into any systematic account of this variety of pulmonary hemorrhage, this arthritic hemoptysis, as I have ventured to call it. But as the cases related have led me to discontinue the ordinary method of treatment by astringents, and to try another method which seems to be more rational, and hitherto at least has proved more successful, I propose to relate two other illustrative cases seen in consultation with other practitioners. Some seven years ago Sir William Jenner, Dr. Wilson Fox, and I were summoned together to consult about a lady suffering from an incoercible hemoptysis. She was a Jewish lady over sixty years of age, very stout, very "rheumatic," and always ailing. She had nodular finger-joints, frequently recurring bronchial asthma, and occasional outbreaks of either eczema or of urticaria. Ten days before our visit, when suffering from an ordinary catarrh without accompanying fever, the patient began to cough up blood, and had continued to do so in small quantities at intervals of three or four hours since. The patient had a somewhat large heart, but there was no murmur, and there was no evidence of systemic arterial disease. Within the previous two days the pulse had become quick and frequent, and the temperature had risen to close upon 100°. In the lungs there were signs of a generalized bronchial catarrh, of emphysema, and of basic congestion. The patient complained of frequent cough, of great oppression of chest, and of growing difficulty in expectorating.

She had, furthermore, a loaded tongue, thirst, loss of appetite, a swollen liver, and all the signs of a gastro-enteric catarrh. She had been carefully treated by absolute rest, fluid food, ice to the chest, and in succession by lead, gallic acid, and hypodermic injection of ergotin. After full discussion, it was determined that another method of treatment should be tried. The patient was ordered to have a light and rather dry diet, to be sparing in the use of liquids, to discontinue the ice, to have a calomel pill at night, followed by a saline cathartic on the succeeding morning, and to take an alkaline mixture with ammonia between meals twice in the day. Within thirty-six hours the bleeding ceased, and the patient made a speedy and complete recovery. About a year and a half ago the patient consulted me at my house for sub-acute rheumatic arthritis. She told me that since she saw me first she had had one attack of bleeding, and that it was quickly cured by calomel and salines.

About six years ago I was summoned to meet Mr. MacLaren in consultation about the case of a solicitor who had been suffering from an obstinately recurring hemoptysis of small amount. The patient was over sixty years of age, had been always delicate and often suffered from incomplete attacks of what was considered to be rheumatic gout. He had rimmed finger-joints, patches of dry eczema, and occasional nervous headaches. A few weeks before our consultation he had contracted a feverish bronchial catarrh and was confined to the house. After a fortnight's cold he began to have some oppression of chest and to be short breathed. This was followed by a small hemoptysis which gave relief, but the hemoptysis recurred, and at our consultation there was no sign of its cessation. The patient had no fever and only a slight hurry of circulation. There was a general bronchial catarrh, the fore parts of the lung were emphysematous, and there was some basic congestion, greater on the right side than on the left. The tongue was furred. There was anorexia with some thirst. The bowels were inadequately relieved, and the urine was pale and of low density, but free from albumin. The patient was directed to rest and keep warm, to live upon a light, semi-solid diet, to be sparing in the use of liquids, to be freely counter-irritated over the chest, to have a succession of small doses of calomel at bedtime, supplemented by saline aperients in the morning, and to take between meals, twice or thrice in the day, a mixture containing iodide of potassium, bicarbonate of potassium, and ammonia. This treatment was not particularly agreeable to the patient, who had medical views of his own. Nevertheless, it was adopted, and appeared so far successful that within four days of its adoption the hemorrhage had ceased. I heard of this patient from a relative some months ago, and I was told, although he led a too sedentary life, he was well and at work.

Many additional illustrations of this variety of hemoptysis could be given, but as in each case there is a close resemblance to each other, and as in all the cases the interpretation of the pathological conditions accompanying the hemorrhage and the treatment employed for its relief were substantially the same, it would be unpardonable to occupy the time of the Society with the reproduction of details which could prove neither interesting nor instructive to the Fellows. I content myself with having brought to the notice of the Society this curious form of pulmonary hemorrhage, and believing that a critical discussion of the subject will lead to a broader and juster views concerning it. I conclude with a statement of the propositions which I have framed out of the results of my own inquiries.

These propositions are as follows:

1. That there occurs in elderly persons, free from ordinary diseases of the heart and lungs, a form of hemoptysis arising out of minute structural alterations in the terminal blood-vessels of the lung.

2. That these vascular alterations occur in persons of the arthritic diathesis, resemble the vascular alterations found in osteo-arthritic articulations, and are of themselves of an arthritic nature.

3. That although sometimes leading to a fatal issue, this variety of hemoptysis usually subsides without the supervention of any coarse anatomical lesion of either the heart or the lungs.

4. That when present this variety of hemorrhage is aggravated or maintained by the frequent administration of large doses of strong astringents, and by an unrestricted indulgence in liquids to allay the thirst which the astringents create.

5. That the treatment which appears at present to be the most successful in this variety of hemoptysis consists in diet and quiet, in the unrestricted use of liquids, and the stilling of cough; in calomel and salines,

in the use of alkalies, with iodide of potassium, and in frequently renewed counter-irritation.

Treatment of Dandruff.

The *Chemist and Druggist*, Oct. 26, 1889, gives the following as being good applications for dandruff. A teaspoonful of either should be well rubbed into the roots of the hair, and then dried with a soft cloth. If the hair is of a dry nature, a little good pomade may be used occasionally.

I.

℞ Tincture of quillaia (1 in 10) . 200 parts
Tincture of capsicum . . . . 5 "
Eau de Cologne . . . . . 20 "
Glycerine . . . . . 30 "
Carbonate of ammonia . . . 3 "
Mix.

II.

℞ Spirit of ether . . . . . 3 ounces
Tincture of benzoin . . . . . 2 drachms
Vanillin . . . . . ½ grain
Heliotropin . . . . . 1½ "
Oil of rose geranium . . . . 2 drops
Mix.

As a pomade the following is recommended:

Salicylic acid . . . . . 30 grains
Borax . . . . . 15 "
Peruvian balsam . . . . . 25 minims
Oil of anise . . . . . 6 drops
Oil of bergamot . . . . . 20 "
Vaseline . . . . . 6 drachms
Mix.

Tapeworm Remedy.

Dr. Numa Canopi recommends the following treatment for the removal of tapeworm. In the evening a dose of castor oil should be administered. The following morning two drachms of thymol divided into 12 doses are to be taken, a dose every quarter of an hour, and after the last dose of thymol, a dose (about five fluid drachms) of castor oil. A few minutes after the last dose of castor oil has been taken the tapeworm will be expelled entire.—*Medical Press and Circular*, Oct. 9, 1889.

Treatment of Ingrowing Toenail.

Dr. Hofmann, of Erlangen, recommends a simple and painless method of treating this complaint. After the part is thoroughly cleansed and disinfected by a sublimate solution, a few drops of liq. ferr. perchl. are dropped on the affected spot. The edge of the nail is then gently raised and then dried. The treatment is continued for two or three days. If suppuration takes place, the hardened scabs should be removed with forceps, and the ferr. perch. again applied. The nail soon becomes soft and brittle so that it can be removed, and without pain.—*Medical Press and Circular*, Oct. 9, 1889.

Rabies.

At a general meeting of the Jamaica Branch of the British Medical Association, held May 29, 1889, at the Public Library, Kingston, Mr. Plaxton read a paper on *Rabies or its "Double."* He related two cases, of which the interest, according to him, was that, admitting them to be cases of rabies, no evil followed bites, or denying them to be rabies, they were cases of an acute and rapidly fatal maniacal affection in the dog. Case I.—One of his own dogs was excited, attacked all his other dogs without more than trifling cause, and bit and struggled when picked up from the ground. He bit five people, including his master. Muscular power gradually failed, the dog seemed to wish to vomit, lay much with closed eyes, whimpered occasionally; eyes clouded; not easily roused; once or twice in the day put his nose to a plate of milk, but did not drink, not seeming to understand it as food; took no note of water; was not snappish. The *post-mortem* disclosed that he had swallowed rubbish of all sorts during his illness. Case II was also that of one of his own dogs, but not infected by the first. On Easter Sunday, 1884, during the night, she killed and ate one of her puppies. She was very furious, and attacked the other dogs, biting three certainly. She never attacked human beings. She tried to destroy a second puppy but was prevented. Water she lapped once or twice, but was not seen to drink any large quantity; milk and meat she treated in the same capricious manner. She was not noisy; never barked; was restless, jumping about the room as if eager to be out. Did not attack human beings. At the *post-mortem* nothing unusual was found; no peritonitis, nothing in the stomach or intestines, no foreign bodies, no rubbish of any kind. If these were not cases of rabies were they interesting cases of insanity in one of the lower animals? The first a case of insanity attacking the subject possibly at

puberty, the second, perhaps, a case of puerperal mania. If they were rabies it was singular that all, man and beast, who were bitten escaped the disease.—*British Med. Journal*, Oct. 5, 1889.

To Abort Cold in the Head.

The *Chemist and Druggist*, Oct. 26, 1889, claims that the following formula will frequently abort a cold in the head, if taken at bedtime on the day the cold makes its appearance:

℞ Tr. camph. comp. . . . . f℥j
Tr. cinchon. comp. . . . . f℥ij
Sp. æth. nit. . . . . f℥ij
Aquam. ad . . . . . f℥ij
Ft. haust.

Prophylactic Hair-wash.

The following hair-wash, given among the selected prescriptions in the *Journal of Cutan. and Genito-Urin. Diseases*, Oct., 1889, and quoted from the *Therapeutische Monatshefte* for July, 1889, is said to keep the scalp cool and the hair dry and free from oil, also to prevent dandruff, besides being a most agreeable toilet preparation:

℞ Spirit. etheri . . . . . f℥jss
Tinctur. benzoini . . . . . f℥jss.–f℥ij
Vanillin . . . . . ♏j
Heliotropin . . . . . ♏iij
Ol. geranii . . . . . gtt. j
M. Sig.: For hair-wash. Keep well corked and do not expose to flame, as the mixture is highly inflammable.

Artificial Food for Infants.

Dr. Escherich, of Munich, gave a lecture in the Pædiatric Section of the sixty-second meeting of German naturalists and physicians at Heidelberg, advocating a reform in the artificial feeding of infants. He bases his belief in the necessity of such a reform on the errors produced by Biedert's theory, which depends upon the difference between cow's milk and normal human milk. Biedert's view was, that all the troubles and diseases occurring in artificially-fed infants were due to the indigestion of the caseine of the cow's milk, causing irritation of the mucous membrane of the bowels. He therefore considered that if the latter were diluted so as to contain 1 per cent. only of caseine, the infant could not possibly take an injurious quantity of this noxious substance. Dr. Escherich considers that this theory and the practice resulting from it have gone far to prevent due care being exercised as to much more important conditions. Such are, according to the lecturer, germs and fermentation in improperly kept cow's milk, the number of meals, and the quantity of food given at a time in proportion to the capacity of the infantile stomach, the total quantity of nutritious matter and its proportion in the food, and finally the injurious effect which the water which has been added to the food has on the digestion and the metamorphosis of nutritious matter. Dr. Escherich holds it above all necessary to return to physiological principles, and so to approximate artificial feeding as much as possible to the mother's milk, as regards the absence of germs and the number and quantities of meals. The lecturer then pointed out that it is easy enough by sterilization of small quantities of milk according to Soxhlet's plan to comply at least theoretically with all these conditions, and at the same time to limit the quantity of caseine so as to fulfil Biedert's requirements.—*The Lancet*, Oct. 26, 1889.

Eucalyptus in Scarlet Fever.

The profession is greatly in need of a safe and agreeable antiseptic for use in cases of infectious disease and offensive cancerous ulcers—one readily tolerated by the patient. Carbolic acid and iodoform are both offensive and poisonous, but the oil of eucalyptus, which is a strong antiseptic, can be used freely without danger to the patient. Mr. J. B. Curgenven says, in the *British Medical Journal*, Oct. 26, 1889, that he has used it in the treatment of scarlet fever with complete success. Four cases were treated; each was in a family where there were other children who had not had the disease. In these cases the fever disappeared in a few days, and at the end of a week or ten days joined the rest of the family without communicating the disease to any of them. There was no general desquamation; it occurred only on those parts where the rash was thickest.

The remedy was used both internally and externally; one to four drops of the oil in emulsion being given every four hours, and the entire body being frequently washed with a solution of the drug. The entire

room and bedding should also be sprayed with the solution. This is to be done night and morning for the first few days, then each night until the end of ten days. The head and hair are also subjected to the same treatment every three days. At the end of a week the bath with the use of the eucalyptus soap is used every night, the eucalyptus solution being rubbed over the skin afterwards. The free use of this antiseptic is not attended by any ill effects whatever, either to the patients or to those in attendance.

Ergot in Cholera.

Surgeon-Major Comerford, of India, has recently been using the fluid extract of ergot with marked success in the first stages of cholera and in severe diarrhœa. The drug was used hypodermically in ten minim doses. In every instance its use was followed by complete success, the diarrhœa being quickly checked and collapse averted. These results were, however, only obtainable during the first stages of the disease.

Antipyrin in Diabetes Insipidus.

Since the publication of a note by Eichhorst who reported the case of a man, 38 years of age, suffering from diabetes insipidus, in whom the daily amount of urine was reduced from thirteen quarts to normal by the administration of seventy-five grains of antipyrin daily, the value of this remedy in diabetes insipidus has been the subject of considerable discussion. The remedy has also been claimed to reduce the renal secretion in diabetes insipidus. The usefulness of antipyrin in the latter affection has been still further strengthened by the report of three cases published by Dr. M. Opitz in the *Deutsche Medicinische Wochenschrift* for August 8, 1889. These cases show that after the prolonged but fruitless employment of numerous other remedies, the subjective symptoms of diabetes insipidus, as well as the amount of urine eliminated, yielded to the administration of antipyrin. In one of these cases a permanent cure was said to be obtained; in another the cure persisted some time after the suspension of the drug; while in the third case the amount of urine returned to its original volume after the cessation of the use of antipyrin, but was again reduced to normal when the drug was readministered. With this reduction in the amount of urine secreted, there was decrease in thirst, improvement in the general feelings, increase in the body-weight, and undisturbed sleep returned. These cases seem to show that the result was directly attributable to the antipyrin, for in one case the disease had lasted more than twenty years, and had been rebellious to the most varied forms of medication, while in another the amount of urine eliminated daily reached the enormous quantity of sixteen quarts, and was yet cured by the use of the drug.—*Therapeutic Gazette*, Oct., 1889.

Multiple Epitheliomata.

An interesting case of multiple epitheliomata is recorded in a recent number of the *Lyon Medical*, by M. Lacroix. The patient, a man aged 78, was under the care of M. Mollière. In 1881 he was operated on by the latter, and a warty tumor removed from the dorsum of each hand. At the same time there were to be seen tumors of various forms and of cutaneous origin upon the forearms and cheeks. These lesions, according to the author, were interesting from several points of view; first, because of their multiplicity and variety; second, on account of the situations of the lesions upon the cutaneous surfaces exposed to the air; thirdly, because of their slow development, and their relative signs of benignancy. As far as treatment was concerned, the multiplicity of the growths precluded the opportunity of adopting radical measures.—*Med. Press and Circular*, Oct. 23, 1889.

Cinchona Cultivation.

The cultivation of cinchona bark in Ceylon has been so extended of late years, that the bark is at present almost a drug in the market, and the price of quinine has fallen lower than the most sanguine ever imagined. Welcome as this fall in price must have proved to medical men and medical institutions with whom in years not long past the cost of quinine was an important item of expenditure, it is viewed otherwise by those who are financially interested in the plantations, and a movement is now on foot, having for its object a limitation of its production. It is proposed to effect this by means of a syndicate, which will regulate the export and prevent glutting of the market.—*Med. Press and Circular*, Oct. 23, 1889.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

REMOVAL OF LARGE PARTS OF THE LIVER.

In an Editorial in the REPORTER, October 12, 1889, attention was called to the experiments of Professor Ponfick, of Breslau, in regard to removal of portions of the liver, recently reported in abstract. A full account of these experiments is given in the *Archiv für pathologische Anatomie und Physiologie*, November 2, 1889, and deserves careful study.

Ponfick performed his experiments upon rabbits, because these animals are easy to get and easy to operate upon. His paper mentions a number of investigations which preceded his own, and describes the latter with admirable clearness. He classifies the dangers connected with these operations as of three kinds: first, the danger of peritonitis; second, the danger dependent upon the loss of parts of such an important gland; and, third, the danger connected with such a radical disturbance of the fetal circulation. In operating, he found that the use of antiseptics—except in very dilute form or small quantity—was a source of danger; so he came to avoid corrosive sublimate altogether, and to use carbolic acid in solutions no stronger than two per cent., and iodoform only very sparingly. As to the method of operating, he tried and abandoned the use of the galvano-cautery, the Paquelin cautery, and chemical cauterants, and found the best method to be with the knife and ligature.

As a result of his experiments he found that total ablation of the liver in one operation was always fatal, but that, by taking away part of it at a time, he could remove a very large portion without seriously impairing the health of the animal. He discovered no reason to believe that different parts of the liver exercise different functions, or that it made any difference what part of it he removed, provided the relative quantity was the same.

In detail, he found that rabbits may recover and thrive after removal of about one-fourth of the liver at a single operation; then, that after removal of half of the liver they lived for weeks and months, and actually improved in condition. He then tried removing three-fourths at one time. This he did twenty-eight times; and seventeen of the animals experimented on died within fifty hours; eight lived from fifty to one hundred and fifty hours; and three lived for periods ranging from thirty-two to seventy-seven days. In eight cases he removed three-fourths of the liver, and, when the animals were restored to good condition, took out the remainder. All these animals died promptly—within twenty-six hours; but he thinks this was not due to the loss of the liver substance, attributing it rather to the severity of the operation. In six cases he removed four-fifths of the liver at one time; and all the animals died within sixteen

hours. In eighteen cases he removed, first, about a fourth of the liver; and then, when the animals were quite well again, nearly another fourth; and, when they had entirely recovered from this operation, as nearly all the remaining portion as he could. One of these animals lived for sixty hours.

In conclusion Ponfick suggests that, with an improved technique, it may yet be demonstrated that practically the whole of the liver may be removed without causing the death of the animal from which it is taken.

The results of these experiments are of the highest scientific and practical interest, and suggest—as we have before intimated—important modifications of prevailing views in regard to the physiological function of the liver, as well as in regard to the limitations of surgical treatment of this organ. Ponfick himself points out some striking lessons to be drawn from a comparison of the effect of his experiments with the clinical phenomena of acute and chronic diseases of the liver, and promises investigations in regard to the physiological effect of the removal of large portions of the liver upon the animal organism, which will be looked for with the most interested expectations.

TREATMENT OF GUNSHOT WOUNDS OF THE ABDOMEN.

The city of New York furnishes a large number of cases of gunshot wounds every year, and many of them come under the notice of hospital surgeons of great skill and experience, and for this reason the opinion held in that city in regard to the proper method of treating such cases deserves the most careful consideration. At a recent meeting of the New York Academy of Medicine, Dr. Lewis A. Stimson read a paper on the subject, in which he spoke of having treated no less than twenty cases of bullet wounds during the past twelve months. He said it was beyond dispute that many lives have been saved in the past five years, which would have been lost if treated in the manner which formerly prevailed. But in judging the merits of the method now most warmly advocated, namely, laparotomy, it is not enough to show that some patients have survived; it is not enough to show that those operated upon would have been saved only by an operation; it must also be shown that it saves a larger proportion of wounded patients than the let-alone method. And, even if this be so, Dr. Stimson said, it is important to decide in individual instances the necessity for an operation or the contrary. During the past nine years there have been over thirty cases of gunshot wounds of the abdomen with laparotomy in the city of New York, and Dr. Stimson has heard of no case in which penetration of the intestine or other viscera was not found. In the New York Hospital since 1876 there have been four cases of gunshot wounds of the abdomen treated without operation, with two recoveries; and one case operated on, which resulted fatally. In the Chambers Street, thirteen cases were treated without operation, with two recoveries; and twelve cases treated by laparotomy, with only three recoveries. In the Roosevelt Hospital there have been six cases treated without operation, with two deaths; and three cases in which laparotomy was performed, all ending in death.

Taking these statistics, the percentage of deaths in patients treated without laparotomy has not been as great as in those operated upon in this way. In regard to the principles which should guide a surgeon in opening the abdomen or leaving it unopened, Dr. Stimson believes that, when a bullet has penetrated the walls of the abdomen it usually causes multiple lesions of the viscera—the most common exception being in cases in which a small bullet enters and lodges in the liver, or when the bullet enters obliquely. In all doubtful cases he thinks—as most surgeons do—that an exploratory incision should be made. If the bullet has lodged in the abdominal walls

or failed to injure the viscera, no harm is done by the operation; if, on the contrary, it has penetrated the viscera, this may be discovered and the wounds can be closed. But to operate after a patient has become practically moribund is to be condemned; for it can only hasten death and bring surgery into disrepute. At such times rest and drainage are the plain indications. Shock Dr. Stimson regards as, in many cases, the effect of extraneous circumstances quite as much as of the injury,—as emotional quite as much as physical.

It is somewhat surprising to find that Dr. Stimson does not approve of the injection of hydrogen gas per rectum, to determine whether perforation exists or not, believing that it is better to do an exploratory operation in all doubtful cases, remembering that it is well to make an opening of fair size rather than a small one through which the gut must be pulled out and examined. He thinks there is no reason to doubt that a ball pursues a straight course through the abdominal cavity; consequently it is not necessary to search for lesions outside of that line, although the movable intestines should all be examined.

This expression of opinion indicates a sort of reaction from the views held by most American surgeons during the past few years, especially since the discovery and announcement of Senn's ingenious method for testing the integrity of the bowel. The readers of the REPORTER are aware that these views have been opposed strongly and with much plausibility by Dr. Paul Reclus, of Paris, as pointed out in Editorials in this journal for May 12, and November 10, 1888, and it will interest them to find at home a surgeon who shares to a certain extent these conservative opinions. Dr. Stimson, it is true, does not share the general opposition of Reclus to laparotomy, as his language quoted above shows; but he does seem to think it worth while to suggest that it is not every case of gunshot wound of the abdomen which calls for laparotomy.

THE SERIOUS CHARACTER OF GONORRHŒA.

One of the arguments in favor of the belief that gonorrhœa is a specific infectious disease is furnished by the results of the disease. Such results as epididymitis or orchitis, abscess of the prostate, cystitis, salpingitis, gonorrhœal rheumatism, and gleet, are comparatively common. But the disease is also capable of affecting the nervous system. In the REPORTER, September 22, 1888, reference was made to the manifestations of gonorrhœa, as affecting the spinal cord, and in the *Allgemeine med. Central Zeitung*, No. 41, 1889, Dr. Samter communicates an account of a case in which trismus and tetanus followed a gonorrhœal orchitis. The patient in whom this occurred was a man, twenty-eight years old, who presented the characteristic symptoms of trismus and of tetanus; the tetanic spasms affected all the muscles of the skeleton, except those of the arms. The patient had not been subjected to any injury; but he had had a gonorrhœa complicated with orchitis, and, a fistula being established in the left testicle, the latter had been completely destroyed. Dr. Samter believes that it was this fistula which caused the tetanus. The result of treatment was very fortunate: the tetanus disappeared under a daily dose of seventy-five grains of chloral, and the fistula was also healed.

Perinephritic abscess is an occasional sequel of gonorrhœa. A case of the kind is reported in the *Medical Press and Circular*, May 16, 1889, by Dr. Astley Bloxam. The patient had contracted gonorrhœa in 1884, and the disease had become chronic. At the end of about three years he was seized with pain in the right lumbar region. The pain was aggravated by walking, and to such a degree that he could no longer move. A tumor of irregular form developed in the region of the right kidney, and was diagnosticated by Bloxam as a deep abscess. The abscess was incised and the collection of pus, which was seated under the transverse

aponeurosis around the right kidney, evacuated. At the end of fifteen days the patient was considered well.

A very rare complication of gonorrhœa is pyemia. Dr. Roswell Park reports a case of the kind in the *New York Medical Record*, September 22, 1888. The patient was a man who, in the course of a gonorrhœa, presented symptoms of pyemia of a typhoid form, to which he succumbed. At the autopsy, pus was found in both knee-joints and in the left sterno-clavicular joint. The pus, however, did not contain gonococci.

The mention of the preceding cases will be sufficient to indicate the uncertainty that attends a case of gonorrhœa. One can never tell what the possible result may be. The late Dr. Maury, of Philadelphia, used to express the apprehension which the physician feels when treating a case of this disease, by saying, that he would rather have any one ring his door-bell than a person with gonorrhœa. Moreover, as regards the permanency of its lesions, gonorrhœa is as much to be dreaded as syphilis. The multiplicity and permanency of the results of gonorrhœa indicate the specific character of the disease, and if they were better understood by laymen this might possibly lead to a greater chastity. This is doubtful, however; but considering the relative importance of the two diseases, gonorrhœa and syphilis, we can see no adequate reason for refusing to admit patients with the former disease to the large hospitals which are admitting freely patients with syphilis. Both are a serious menace to the health and happiness of many besides the persons immediately concerned, and in both freedom from complications and sequelæ can be attained only by judicious treatment for a considerable time, and by suitable control over the patients in the interval.

Professor Brieger has received the sum of fifteen hundred marks to enable him to prosecute his studies of the ptomaines.

THE RESTRICTION OF HYPNOTISM.

At a meeting of the Contemporary Club, in Philadelphia, November 12, 1889, Professor George S. Fullerton, of the University of Pennsylvania, delivered an address on "Hypnotism," illustrating it by experiments on several intelligent subjects. Dr. George M. Gould spoke strongly against hypnotism and opposed its unrestrained practice, saying that a mesmerist is not always a moral man, and on account of the evil that is possible from the actions of those who may have others under the control of their more powerful will, its investigations should be limited to careful and studious men, and for others it should be suppressed by law.

There can be no doubt that this is a sound opinion, and that no one should be permitted to enter this perilous field of investigation without the most ample scientific training for it, and the most conscientious determination to use its opportunities only for the good of mankind.

CHICAGO AND THE CODE.

The *Medical Standard*, which is published in Chicago, speaks at times with great plainness of the failings of the medical profession in that town. In its issue for November, 1889, it says editorially: "The question whether the code of the American Medical Association rules even the Chicago followers and satellites of the local 'Fathers in medicine' is a decidedly open one. About half a score of cases of disease 'seen with' disciples of Hahnemann and Thompson have been reported in very recent articles in the *Journal of the American Medical Association*. The New York code seems to have many secret followers, even among the blatant eulogists of the American code. If the code is a sacred law it ought to be enforced. Hypocrisy of the type described is more destructive to the morale of the profession than any New York code."

This is a statement which may be en-

dorsed irrespective of its applicability to the case in hand. It is to be hoped that the *Medical Standard* is mistaken about the behavior of the followers of the "Fathers in medicine" in Chicago, or that the latter will mend their ways.

The time is coming, we trust, when "straightness" will be indispensable to even apparent success in the profession of medicine, and we incline to the opinion evidently held by the *Medical Standard* that one way to hasten this desired consummation is to point out examples of crookedness. This may not be pleasant to those who find in it a duty or to those who find in it a punishment; but it does seem as if it ought to be done. The silence of influential medical journals is undoubtedly responsible for the appearance of approval which has been permitted toward manifest misconduct on the part of members of the medical profession, of medical schools and even of medical journals.

MASSAGE IN A VILE ROLE.

The officers of the Society to Protect Children from Cruelty, in Philadelphia, on November 21, followed up some recent exposures by the *Press*, of this city, by breaking up an establishment ostensibly devoted to bathing and massage, but which was specially characterized by the fact that in it the massage was administered to men by comely young women. Investigation led to the belief that the administration of massage in this way was not intended solely as a therapeutic measure, and that the services of the *masseuses* were not limited to this function alone.

This is not the first time that this disgraceful mode of furnishing sensual pleasure has been heard of, but it is to be hoped that the officers of the law will now find some way to suppress it utterly. Medical men have long been aware of the dangerous possibilities of massage, but probably very few of them have ever had any knowledge that it had been made a means of sensual gratification. Such occurrences as are now attracting attention in Philadelphia, however, will direct their attention to it anew, and may put them on their guard against the danger which may be associated with it. More than this, medical men outside of Philadelphia may know of other cases of misuse of massage, and may be in a position to aid the authorities in detecting and punishing those who are debasing it to improper ends.

It would be very unfortunate if so useful a therapeutic measure were to fall into disfavor because the community regarded it as likely to be a source of moral danger; and it is to the interest of science and of practical medicine that medical men and women should do what they can to prevent so deplorable a result.

This is a matter which we would not care to comment on, were it not that so much is being said about it in the daily newspapers, and that we believe it to be one in which the medical profession is specially concerned and in which its members may well exercise the office of guardians of the public morals.

CORRESPONDENCE.

Correction.

To the Editor.

Sir: Please rectify in your next issue, the following typographical error: "How rarely when such a patient has recovered does his physician doubt that alcohol has contributed, etc., etc." It should read, "How rarely, etc., etc., has his physician *no* doubt that alcohol, etc., etc." The error occurs on page 510, lower third of second column.

Yours truly,

J. Chris. Lange.

Pittsburgh, Pa.,
Nov. 11, 1889.

Danger in Silk Thread.—Silk thread, says *Sanitary News*, is soaked in acetate of lead to increase its weight, and persons who pass it through the mouth in threading needles, and then bite it off with the teeth, have suffered from lead-poisoning.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

DU SANG ET DE SES ALTÉRATIONS ANATOMIQUES. Par Georges Hayem, Professeur a la Faculté de Médecine de Paris, etc. (The Blood and its Anatomical Changes, by Georges Hayem, etc.) With 126 illustrations, plain and colored. Large 8vo, pp. xxvi, 1035. Paper cover. Price, 32 francs.

The author of this magnificent volume states, in the preface, that "the future belongs to hematology. It will bring in the solution of the great questions of nosology." Certainly, if any one is justified in such an expectation, it is Dr. Hayem, who may be said to be the finest and most accomplished student of the blood now living. Few medical men can be fully aware of the wonderful achievements he has made in determining the actual conditions of healthy blood and the changes which the blood undergoes in its normal development and pathological states. In the book before us these are fully and clearly described, as well the steps by which the investigation of the blood may be conducted by those who wish to search in this field. In addition Dr. Hayem discusses most ably the relation of different alterations of the blood to different morbid processes of the organism in general, and in so doing adds practical utility to the extreme scientific interest of his work.

In our space we can do no more than outline the scope of this great and handsome book, commending it most warmly to the attention of our readers.

CYCLOPÆDIA OF THE DISEASES OF CHILDREN, MEDICAL AND SURGICAL. THE ARTICLES WRITTEN ESPECIALLY FOR THE WORK BY AMERICAN, BRITISH, AND CANADIAN AUTHORS. Edited by John M. Keating, M. D. Vol. II. 8vo, pp. xii, 1066. Illustrated. Philadelphia: J. B. Lippincott Company. 1889.

The second volume of this magnificent work contains articles on Diseases of the Skin; Constitutional Diseases, and Diseases of Nutrition; Diseases of the Respiratory Tract, including the Pharynx; Diseases of the Circulatory, Hæmatopoietic, and Glandular Systems; and Diseases of the Mouth, Tongue, and Jaws. The writers are among those most widely known in America and Great Britain, and it goes without saying that a high order of excellence characterizes the articles. The encyclopædic nature of the book may be judged from the fact that there are papers on Scurvy, Cretinism, The Urinary Diatheses, Diabetes Mellitus, and Asthma. These are subjects rarely more than mentioned in works on diseases of children; but in the present one they are ably handled by Drs. Thomas Barlow, Judson S. Bury, the late J. Milner Fothergill, George B. Fowler, and Frederick C. Shattuck. A melancholy interest attaches to Dr. Fothergill's article from the circumstance that it was the last one written by him; it was received by the Editor a few days after a cable message announced the author's death.

Dr. H. R Wharton contributes a valuable paper on Tracheotomy. The operation is well described; its indications, and the results to be hoped from it are clearly stated; and the more important instruments and appliances illustrated. It is plain, practical, and to the point throughout, and will fully repay careful reading.

It must always happen that in a large work such as this there will be some articles of greater merit than others; but it is a great pleasure to say that we have seen no poor ones. It is high praise to say that the present volume comes fully up to the expectations raised by the first. We cannot do better than express the hope that the remaining volumes will not fall below the standard of these; the complete work will then be unique in English literature of diseases of children, and will rank with Gerhardt's "Handbuch der Kinderkrankheiten."

TRANSACTIONS OF THE SOUTH CAROLINA MEDICAL ASSOCIATION. Thirty-ninth Annual Session, held in Charleston, S. C., April 23 and 24, 1889.

This volume contains a number of interesting papers by prominent members of the South Carolina Medical Association. The address of the President, Dr. C. R. Taber, of Fort Motte, on "Modern Materialism in Modern Medicine," is an earnest and eloquent plea for the recognition of the spiritual in science, especially in medical science. Dr. Robert Battey, of Rome, Ga., devoted his address to some remarks bearing upon the ovular theory of menstruation, and to insisting upon the propriety of ovariotomy for certain grave neurotic troubles.

Dr. E. Peyre Porcher, of Charleston, reports fifteen cases of hydrothorax, his sixth series of cases. He thinks that a vast number of cases throughout the country escape detection and treatment, either medical or surgical. Dr. A. B. Patterson, of Barnwell, reports a curious case in which a glass ball remained in the cavity of the uterus for fifteen years. It was removed when discovered, and the patient made a speedy recovery.

The "Transactions" contain many other instructive and valuable papers; the volume as a whole is creditable alike to the individual contributors and to the Association.

AN INTRODUCTION TO PATHOLOGY AND MORBID ANATOMY. By T. Henry Green, M. D., Physician to Charing Cross Hospital, etc. Sixth American from the Seventh English Edition. Revised and enlarged by Stanley Boyd, F. R. C. S. Eng., Senior Assistant-Surgeon to Charing Cross Hospital, etc. Illustrated by one hundred and sixty-seven fine engravings. 8vo, pp. xx, 523. Philadelphia: 1889. Price, $2.75.

The present edition of Green's "Pathology" differs materially from the preceding edition. Mr. Boyd has recast the chapter on Fatty Degeneration, and has made considerable changes in the accounts of other degenerative processes; he has rewritten the section on the Etiology of Inflammation, and much of the chapter on the Vegetable Parasites, and has made numerous additions to the accounts of the Infective Granulomata, including the insertion of a section on Rhino-scleroma. The number of illustrations, which always have been an excellent feature of the book, has been increased; the cuts made from microphotographs, and illustrating for the most part diseases of the vessels and of the spinal cord, deserve special praise. The book is larger than in the preceding edition, but not very much, the increase being chiefly in the use of larger type for the headings and subdivisions of chapters.

This is not an ordinary new edition; it bears evidence throughout of having been subjected to thorough and careful revision. The revision has been done

so judiciously, however, that the features of the book which made it so valuable as a manual for students have been retained, while the pathological information presented is more comprehensive in its scope and brought nearer to date. We unite with Mr. Boyd in regretting that Dr. Green has withdrawn his guiding ha d from the work, but are glad that he has found such a capable successor.

QUESTIONS AND ANSWERS WITH ESSENTIALS OF MEDICAL CHEMISTRY. By Lawrence Wolff, M. D., Demonstrator of Chemistry, Jefferson Medical College, etc. Small 8vo, pp. 214. Philadelphia: W. B. Saunders. 1888. Price, $1.00.

Medical chemistry has been well defined as that part of chemistry which relates more particularly to the wants of the practitioner, and we could wish that more books like this would be written, in order that medical students might thus early become more interested in what is often a difficult and uninteresting branch of medical study. There are mistakes, omissions and discrepancies to be found in the work, but the general make up and plan are excellent. The index is well prepared and a valuable addition. We note a few errors and omissions, which will doubtless be corrected in later editions. For example, on page 41, Cl is called a heptad, and N a diad; while in Fehling's Solution, page 181, the sp. gr. of NaO^1H is put at 1.34 instead of 1.14. The potassium ferrocyanide test for albumin might also be inserted, as well as a description of the method of performing a combustion.

Notes and Comments.

Segmented Ring for Intestinal Anastomosis.

At a recent meeting of the Southern Surgical and Gynecological Association, at Nashville, Dr. A. V. L. Brokaw, of St. Louis, Mo., read a paper entitled, "Intestinal Anastomotic Operations with Segmented Rubber Rings, with some Practical Suggestions as to their use in other Surgical Procedures." The paper considered in detail the results obtained in an experimental study of all the anastomotic operations, and an original, technique and application of segmented rubber rings, in such operations as gastrostomy, duodeno-cholecystotomy, jejuno-cholecystotomy, ileo-colostomy, and circular enterorrhaphy. Reference at length was made to the author's success in closing very large wounds of the intestines by the use of a single segmented rubber ring, formed of eight short sections of tubing. The ring being introduced into the intestines, is bent evenly upon itself and the apposition threads being tied, perfect, safe closure of the largest wound is accomplished without stenosis following. The ring devised by the author is very simply constructed by passing a double strand of catgut continuously through from four to eight short sections of rubber drainage tubing of a diameter from one-sixteenth to one-fourth of an inch. To the catgut within the rubber sections are tied the apposition threads. The segmented rubber rings are applied in the anastomotic operations in the same manner as Senn proposed in the use of his bone plates. The advantages of segmented rubber rings over other procedures and devices, is the rapidity with which they may be made, during an operation if need be. In the absence of proper tubing pieces of catheter could be substituted. For the closure of small wounds in the intestines a new suture was proposed. Short rods of decalcified bone, one-sixteenth of an inch in thickness and one-fourth of an inch in width, are perforated at points less than half an inch apart for the passage of the apposition threads, which are attached in this manner: a strand of chromicized catgut or well prepared juniper catgut is doubled, and a single knot is made in the middle of this doubled catgut strand (silk may be used if preferred), and the loop and end threads are passed through the small openings made in the decalcified bone rods. Each thread and loop is threaded to separate needles, the rods are introduced in the wound in the bowel, the needles are passed from within outward less than a quarter of an inch from the wound margins and the loops and single threads are tied in pairs. For this method Dr. Brokaw claimed accurate, rapid, and safe closure of small wounds of the intestines. He preferred a segmented rubber ring in the closure of large wounds.

A description of two new wholly absorbable apposition rings was given, which had experimentally shown most excellent results. One was formed by decalcifying the long bones of chickens and young animals: the process of decalcifying being the same as for making bone drainage-tubes. With short sections of bone so prepared and a double strand of catgut, the rings were made in a manner similar to the described segmented rubber rings. The second wholly absorbable ring was made of short sections of the arteries of large animals. After dissecting the arteries up from their sheaths, they are cut in short segments, boiled five minutes, and into the lumen of each section a glass rod is pushed, and they are then immersed in alcohol for a few days. When the rods

are withdrawn, the hardened artery tubes are ready for use. With four to eight short sections of arteries so prepared, approximation rings are easily made by passing a double catgut strand continuously through the lumen as described previously. These rings serve their purpose admirably, are easily made, give a good-sized aperture, and are entirely absorbed in a few days. Experiments were made upon over fifty dogs by the above methods.

German Hospital in Philadelphia.

The German Hospital of Philadelphia had its annual Donation Day, November 28. The administration of this hospital and the care of the sick, in addition to a competent staff of physicians, is entrusted to experienced and devoted German Deaconesses. The hospital has a superior sanitary location, adjoining Girard College, and a large number of comfortable private rooms, which make it a desirable abode in sickness for well-to-do patients. The management has adopted a plan of subscription for persons of moderate means, who can thus, by small monthly contributions, secure free treatment in sickness for themselves or others.

Needle in the Breast, with Communicated Pulsation.

At a recent meeting of the Boston Society for Medical Improvement Dr. Wyman showed a needle which he had removed from the breast of a child eight months old.

The history of the case was as follows: The child was brought to his office, the mother thinking there was something alive in the right chest. On examining, Dr. Wyman found, midway between the nipple on the right and the central line of the sternum, a pulsating area a little smaller than a quarter of a dollar. The skin was red and the pulsation could be plainly seen and felt. In the centre there seemed to be a foreign body, which felt like the head of a pin moving with each pulsation of the heart. The heart-sounds were found to be normal. As the diagnosis was doubtful, Dr. F. C. Shattuck was called in. The prominent point was cut down upon and a needle was found and withdrawn. The direction of it seemed to be toward the right ventricle. The child got well.

Every cardiac systole was distinctly communicated to the foreign body, which must have been in immediate contact with the heart valve or pericardium, if its point was not imbedded in the muscle of the right ventricle.

Dr. George L. Peabody, of New York, showed a year ago in Washington at the meeting of the Association of American Physicians a pin which was imbedded in the wall of the left ventricle and a portion of which projected into the cavity. It was evident from the condition of the pin and the presence of a cicatrix that the pin had lain there for some time. The immediate cause of death seemed to have been Bright's disease. At the time of Dr. Wyman's report, Dr. T. M. Rotch said it was possible that in this case the foreign body had penetrated the heart. About a year ago he showed a slate pencil, which in all probability had penetrated one of the ventricles. The child recovered.

Complications of Gonorrhœal Rheumatism.

A. C. Bornemann, of Copenhagen, has recently described the various forms of complication which are met with during an attack of gonorrhœa, of which the symptoms are analogous to those attributable to rheumatism. The most common seat of so-called gonorrhœal rheumatism is that of articulations; then follow the tendons, the periosteum, nerves, muscles, eyes, and lastly the pleura. The author's observations were based upon 278 cases of patients suffering from gonorrhœa, who came under treatment in the wards of the hospital at Copenhagen. In these patients the knee was affected 240 times, the foot 151, the shoulder 68, the metacarpo-phalangeal joints 52, the other articulations of the hands 51, the hip 46, the elbow 45, the jaw 12. The presence of increased amount of fluid in the synovial sacs was frequent but not constant; for example in the 240 instances in which the knee was affected, the excess of fluid was noted in 183 times. Affections of the tendons and synovial bursæ occurred in 41 patients; four other patients suffered from periostitis; while there were three cases in which muscles were attacked. Out of this number of 278 patients the author met with two cases of endocarditis, gonorrhœal ophthalmia was comparatively frequent, having

developed in 45 instances, and sciatica occurred five times. With reference to the question of the discovery of the gonococcus in the synovial fluid of a joint attacked with gonorrhœal rheumatism, confirmation of the statement is still wanting. The author has found several times in the synovial fluid of the knee after puncture, micro-organisms which do not comport themselves like gonococci. He believes them to be identical with the cocci found in the tissues invaded by suppurative processes.—*Med. Press and Circular*, Oct. 23, 1889.

No Mortuary in Paris.

Efforts have been made on various occasions to provide mortuaries in Paris for persons who, for any reason, were not domiciled anywhere at the time of their death. A painful instance of the inconvenience resulting from the want of them occurred last month and is referred to in the *Med. Press and Circular*, Oct. 23, 1889. A journalist, in the last stage of phthisis feeling better one day, took advantage of this to induce his brother to bring him in a cab from the outlying suburb, where he had been residing, into Paris. He, however, succumbed soon after passing the *barrière*, and then began, for the brother, a tedious and horrible promenade. Refused at his own hotel, declined at the hospital, on the ground that it was not a mortuary, rejected at the Morgue, because only the unidentified dead are received there, the whole night was passed in perambulating the streets in the cab with the dead body of his brother that nobody would receive. It was only by a derogation from the rules of one of the hospitals that the brother was enabled to find a temporary resting place for the deceased.

Colored Spectacles.

Dr. Königstein, while giving directions in his class on the uses and prescribing of spectacles, said that green glass as a protection against strong rays was worse than useless, and did more harm to a sensitive eye than good, as they allowed the yellow rays to be transmitted and unnecessarily irritate the eye. As a protection against strong rays the blue or smoked glasses were the only real protection. The blue should be light, as a deep blue color produces a clear violet disc in the centre of the lens which apparently corresponds to the fovea centralis, and by a protracted use of dark blue spectacles the patient may become annoyed by the mosaic work of the fundus of the eye appearing before him. The phenomenon seems to be connected with the pigment changes in the macula lutea.—*Medical Press and Circular*, Oct. 2, 1889.

Chrysarobin for Hæmorrhoids.

Dr. Kossobudskii speaks of this drug in high terms, but he differs with Unna as to the proportion to be used in the ointment employed. Dr. Kossobudskii uses two and a half per cent. instead of five per cent. of chrysarobin as Unna prescribes. After washing the swelling with a two per cent. lotion of carbolic, or a one per cent. lotion of creolin, he applies the following ointment twice or three times a day:—

℞ Chrysarobini . . . . . gr xij
Iodoformi . . . . . gr jvss
Ext. belladonnæ . . . . . gr jx
Vaselini . . . . . ʒjv
M. et fiat ung.

Or a suppository may be made with cocoa butter. If bleeding be present tannin may be combined in the above formula. Dr. Kossobudskii affirms that the pain, smarting, and bleeding will disappear in three or four days under this treatment.—*Medical Press and Circular*, Oct. 2, 1889.

The Removal of Hairy Moles.

Hairy moles frequently occur upon the face or upon other exposed portions of the skin. Heretofore the removal of these blemishes has been effected by means of the knife, electrolysis or caustics. The first and last methods are limited in their applications by the extent of the mole. The second method is frequently tedious. A new procedure is to apply ethylate of sodium, one thorough application being sufficient. A bland ointment is used as a dressing, and the result is a very thin, flexible scar which is scarcely perceptible. Of course, the ethylate of sodium is applied to the patient only under chloroform, as it is exquisitely painful.—*Medical Chips*, Sept., 1889.

NEWS.

—A New Hospital for chronic invalids will soon be opened in New York, it is to be called the Isabella Heimath, and will be non-sectarian.

—The Episcopal Hospital in Philadelphia is now prepared to furnish nurses from its Training School, either for private cases or for institutions.

—The "Charity Club," a philanthropic institution of Boston, is said to contemplate the establishment of a new hospital for the surgical treatment of diseases of women.

—The seventieth birthday of Professor Bardeleben, of Berlin, was celebrated October 15. A marble bust of the well-known teacher was unveiled in the garden of the Charité Hospital, in Berlin.

—Dr. J. Emerson Kent, well known as an author, inventor, and physician, died in Philadelphia, November 20, 1889. He was born in 1811, in England, and was graduated from King's College, London, in 1839.

—The New York Board of Health decided, on November 19, to resort to radical measures to rid the city of the stenches caused by the manufacture of gas. The Board is prepared to carry its case into the Courts.

—Professor Wm. Pepper, of Philadelphia, will deliver the Middleton Goldsmith Lecture before the New York Pathological Society, in the hall of the Academy of Medicine, on Wednesday evening, January 15, 1890. The subject of the lecture will be "Hepatic Fever."

—Miss Clara Barton, the president of the Red Cross Association, left the Conemaugh Valley, October 25, closing the greatest campaign the Red Cross has hitherto enlisted in. A public reception was given Miss Barton before she left, which was largely attended by all classes.

—Dr. Brown-Séquard is still actively engaged in experimenting with his "Elixir of Life,"—which he does not call by this term, however. He is very sanguine as to the ultimate success of the fluid, and intends shortly to publish the results of his investigations in the *Archives de Physiologie*.

—The City of Brooklyn proposes to increase its supply of water by a ten-mile extension to Massapequa Pond, and has received bids for the work. The successful bids aggregate $3,071,000, which exceeds the estimate of the engineers. The largest excess over estimate is in a section where a very heavy iron pipe is necessary, and is due to the appreciation in the price of that metal.

—The Russian Academy of Sciences offers a prize of 5,000 roubles ($2,500) for the best inquiry into the nature and effects of the poison which develops in cured fish. The competition is open to all. The memoirs must be sent in, either in manuscript or printed, before January 1, 1893, and may be written in any one of the following languages: Russian, Latin, French, English, German.

—It is reported in the St. Louis *Post-Dispatch* of October 15, that a woman living in Fort Smith, Arkansas, seventy-one years old, gave birth, on October 14, to a well-formed and healthy male child. Two years ago the woman, then a widow, married a young farm-hand employed by her. The case has caused a great deal of excitement among the neighboring physicians and it will be thoroughly investigated.

—The executive committee of the Tenth Annual Charity Ball in Philadelphia has selected four charities to receive the proceeds from the sale of tickets. They are the Sheltering Arms of the Protestant Episcopal Church, which provides for the careful placing of mother and child in proper positions in the country; the Philadelphia Lying-in Charity and Nurse School, the Polyclinic Hospital, and the Visiting Nurse Society.

—On November 18, Dr. J. L. Baker, a well-known dentist of West Chester, Pa., died at his residence from the effects of an attempted suicide by hanging in his stable on November 16. He was found hanging by a halter strap by his assistant, Dr. Scott, who cut him down, and prompt medical assistance seemed to resuscitate him, but death ensued from congestion of the brain. He was 46 years old, and a few years ago was Demonstrator of Operative Dentistry at the University of Pennsylvania.

—The epidemic of cholera, which is now raging in Mesopotamia, first made its appearance on August 14, in Bagdad, and from there spread down the valley of the Tigris. One month later, September 15, 5,393 deaths had been reported, and this figure represented only a small portion of the actual deaths. Numerous towns along the Karun river have been completely deserted. The latest, and most authentic reports state that the disease is still on the increase; many towns along the Persian Gulf and the valley of the Euphrates having become infected.

ENTERED AS SECOND-CLASS MAIL MATTER AT PHILADELPHIA P. O.

EVERY PHYSICIAN prescribing Cod Liver Oil (and who does not?) wants to know that his patients get the best that can be obtained. This is effectually secured by specifying "**BAKER'S**" whose firm (established in 1830) have given the greatest attention to the improvement and perfection of this all important remedy. In the various conditions in which Oleum Morrhuæ is indicated the Practitioner must decide the best form of administration. To meet such conditions we offer:

BAKER'S COD LIVER OIL.

BAKER'S EMULSION WITH HYPOPHOSPHITES OF LIME AND SODA.

Baker's C. L. Oil with Ext. of Malt.

Baker's C. L. Oil, Lime and Wild Cherry.

Above goods are accessible through the wholesale trade to all Retailers, and may be prescribed with the utmost confidence as to Purity and Excellence.

JOHN C. BAKER & CO., PHILADELPHIA, PA.

A Peerless Chemico-Physiological Food and Restorative

Crystalline Phosphate

A TISSUE FOOD

PHOSPHATIC FOOD PRODUCTS TRADE MARK

Contains all essential inorganic components of the tissues in a semi-solid, easily soluble, crystalline mass,

COMPOSED OF

ACID PHOSPHATE OF CALCIUM.

WITH

Acid Phosphate of Magnesium,
" " " Iron,
" " " Sodium,
" " " Potassium,
Chloride of Potassium,
" " Sodium
Sulphate of Potassium,
and Phosphoric acid.

INDICATIONS:

STOMACH DISORDERS, such as Indigestion, Flatulence Gastric Catarrh, and Poor Appetite, Constipation, etc.

WRONGS OF NUTRITION, as in Scrofula, Rickets, Caries, Marasmus, Delayed Union of Fractures, Necrosis of Tissue, Difficult or Delayed Dentition and Development, etc.

NERVOUS AND GENERAL DEBILITY AND SLEEPLESSNESS, as from Sexual Excess, Venerial Disease, Childbearing, Nursing, Loss of Blood or other fluids, Menstrual and other Diseases of Women, abuse of Alcohol, Tobacco and Narcotics, Protracted Illness, etc.

PROF. KONN B. SAYRES, M. D., Demonstrator of Anatomy, Miami Medical College, Cincinnati, O.

I am pleased to inform you that I have during about six months last past made a critical trial of your **Crystalline Phosphate,** in various cases of mal-nutrition, nervous prostration, atonic dyspepsia, insomnia and kindred derangements of the vital functions, which has demonstrated the fact that it is a preparation of *very great value.* I believe your representations concerning it are fully justified by actual and palpable results in my practice, and I very cheerfully recommend it, knowing that a fair trial will prove it worthy of the confidence of the profession.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bed-rooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe, and healthful HOME.

CHRONIC HYDROCEPHALUS.—PRIMARY DENTITION.[1]

BY LOUIS STARR, M. D.,

CLINICAL PROFESSOR OF DISEASES OF CHILDREN IN THE HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA; VISITING PHYSICIAN TO THE CHILDREN'S HOSPITAL, PHILADELPHIA, ETC.

Gentlemen: I wish to ask your attention to-day to the condition known by the laity as "water on the brain," or scientifically speaking, hydrocephalus. A division into acute and chronic hydrocephalus is often made, but the term "acute hydrocephalus" is a bad one, for it merely indicates one result of a very distinct disease, namely, tubercular meningitis. We may put it to one side therefore, and devote our attention to chronic hydrocephalus.

[1] Delivered at the University Hospital.

Chronic hydrocephalus is a condition in which there is an accumulation of fluid, either in the ventricles of the brain or in the subarachnoid space; hence the division into internal and external hydrocephalus. The accumulative fluid is alkaline in reaction and is similar to the normal cerebro-spinal liquid, but has a higher specific gravity and contains a trace of albumin with sodium chloride and urea.

In addition to the divisions based upon the position of the accumulation of liquid, it is customary to divide chronic hydrocephalus into two varieties, viz., the congenital and the acquired.

Congenital hydrocephalus begins while the fetus is in utero, it is the form most commonly met with, and the accumulation of liquid is almost uniformly in the ventricles, or "internal." The quantity of liquid collected varies from a few ounces to several pounds. The causes of this form of disease are obscure, though there is probably always some precedent inflammation of the lining

membrane of the ventricles. Why this should occur is uncertain, but we usually get a history of intemperance, syphilis, rickets or some marked nervous disease, as epilepsy, in one or other parent. It is said also that hydrocephalus is very apt to occur in the children of men who have worked in lead and suffered from lead-poisoning. The cause, too, of congenital hydrocephalus is not a temporary one, for it is very common to find several successive children, born of the same mother, affected by the disease.

The first effects of the accumulation of liquid in the ventricles is exerted upon the brain tissues, the brain substance is thin and the convolutions become flattened. Next the bones of the skull feel the internal pressure and the head becomes distended. The frontal bone is pushed forward; the roofs of the orbit are depressed so as to flatten the sockets of the eyeballs, and the occipital bone and the squamous portions of the temporal bones are forced outwards almost horizontally. By the distending process all the sutures are widened, and the enlarged bulging fontanelles communicate by the sagital suture. The shape of the head is almost always globular. Ossification of the cranial bones is delayed and small islets of bones (Wormian bones) form in the membranous interspaces. From this brief description of the morbid anatomy you can readily see that you must look to the head for the main symptoms of the disease. The head is large and globular, sometimes so heavy that it anchors the child to the bed, the veins of the scalp are dilated and prominently visible, the skin of the cranium seems to be thin and stretched, the hair is sparse and the fontanelles and sutures bulging and distinctly fluctuating on palpation. In contrast with the enlarged head we have a small pale face, presenting a peculiar expression of the eyes, the eyebrows are elevated, probably on account of the stretching of the skin of the scalp, the eyeballs project slightly, the axis of vision has a downward direction and the upper lid is retracted so as to expose the sclerotic above the iris, while the lower lid covers too much of the eye. Generally the frame is wanting in development, and the thin emaciated body presents a marked contrast to the enlarged head. The skin is pale and may be over-sensitive, although anæsthesia is the usual condition, while the muscles are flabby, and there is a marked deficiency in the subcutaneous fat. Of other symptoms I will mention blindness from atrophy of the optic nerve; nystagmus, deafness, impaired intellect, unsteady gait in moderate cases, and absolute inability to walk in serious ones. Among the more marked nervous symptoms are laryngismus stridulus, general convulsions, muscular twitchings, spastic contractions of the limb, and temporary paralysis. Beyond spasmodic breathing the respiration is unaffected and the pulse with the exception of being weak and frequent shows no especial alteration. There is often excessive hunger and sometimes vomiting; the bowels are usually confined though the habitual sluggishness may be interrupted by occasional attacks of diarrhœa.

Of course the gravity of the symptoms varies with the size of the head, *i. e.*, the amount of liquid accumulation; on one hand, patients are seen who, with a moderately large head, present few symptoms, while, on the other hand, one sees cases of immense enlargement of the cranium where the child is unable to move without assistance, has no intellection, and leads almost a vegetable existence, simply eating, breathing, and sleeping. The case that I show you affords a good illustration of what I have said.

The patient, a girl six months old, is the second child, the first having been stillborn. The father and mother are both healthy and one maternal uncle died of epilepsy. The mother states that the child was well formed at birth, and the enlargement of the head was not observed until the fourth month. About this time she began to have convulsions, having on some days as many as six; there was also frequent muscular twitching, spastic contraction of the right arm and leg, and, at times, temporary paralysis of these limbs. The child has shown some disturbance of gastric digestion and occasional attacks of diarrhœa. In this clinical history I would call attention to the statement that the child was born well formed. You will get this history in almost every case of congenital hydrocephalus, for although the disease begins while the child is in utero, the characteristic symptom—enlargement of the head—is rarely noticed until about the sixth month of life. As you see the case to-day you will notice that the child's head is decidedly enlarged and globular in shape and has a tendency to fall to either the one or other side, the skin of the cranium is thin and stretched looking, the hair is sparce and the veins on either side of

the head are quite prominent. On palpation the fontanelles are found to be large and bulging, and the sutures, especially the sagital, widely open. The eyebrows and upper eyelids are somewhat elevated but on account of the moderate degree of enlargement the eyes do not show the characteristic features already mentioned.

You will observe the face is small in comparison to the size of the head, you see also from the pallor of the skin and from the small size of the trunk and limbs that the general nutrition is decidedly impaired. The tongue is somewhat coated, the appetite is poor, and the bowels confined. The two lower incisor teeth are about to be cut. This is an important factor in the diagnosis, as you will see later. Since the administration of bromide, which was begun a week ago, there have been no more convulsions, though a tendency to contraction and twitching of the muscles continues, and there is some hyperæsthesia of the surface.

In this case you see that many of the characteristic symptoms of the disease in question are illustrated. In regard to the diagnosis one point must be borne in mind, namely, that every enlarged head is not hydrocephalus. In rickets the head is often enlarged and the anterior fontanelle long in closing. The shape of the head, however, is square, the increase in size is never nearly so great as in hydrocephalus, dentition is markedly delayed, and we find other evidences of rachitic change in various bones of the skeleton. It must be remembered, however, that rickets and hydrocephalus often exist together. In syphilis, too, the head may be enlarged from thickening of the cranial bones, especially the frontal. Here again the enlargement is less extensive, and unmistakable evidences of the constitutional taint can usually be found upon the skin and mucous membrane.

The prognosis of congenital hydrocephalus is unfavorable, the majority of the patients die before the end of the second year, though in some cases the disease is arrested and individuals have been known to reach adult life and even old age. In these cases the head remains large and unsightly, and the intelligence is more or less blunted. Convulsions, twitching, contraction of the head and other signs of cerebral irritation are unfavorable symptoms. So again are continued wasting and looseness of the bowels. As there is almost uniformly impairment of nutrition, the occurrence of any inter-current disease is apt to prove fatal.

Acquired hydrocephalus is a rare condition and usually occurs before the end of the third year. It is induced by any cause which interferes with the cerebral circulation, such as tumors pressing upon the veins of Galen or straight sinuses, impeding the escape of blood from the ventricles. Enlarged glands pressing upon the veins of the neck may produce the same result. It may also be a consequence of anemia, rickets, and other acute and chronic exhausting diseases which are attended by impoverishment of the blood. Again it may be one element of general dropsy due to disease of the heart or kidneys.

The fluid in acquired hydrocephalus is usually in the ventricles, or internal; it may, however, be found upon the surface of the brain and is then usually a consequence of meningeal hemorrhage.

The symptoms are very similar to those that occur in the congenital form, provided the effusion occurs before ossification of the skull is completed; if, on the other hand, it takes place after the fontanelles and sutures are closed the symptoms are obscure, for there is no distention of the cranium. The child usually becomes dull and heavy, there is headache, vertigo, and often a difficulty in supporting the head, so that the patient lies about and dreads movement. Walking is cautious and tottering, muscular twitching or convulsions come on, the pupils become sluggish and dilated, and the pulse becomes slow. Then there is stupor deepening into coma, and finally death.

The treatment of hydrocephalus is most unsatisfactory. One should endeavor to keep the child's digestion in good condition and to maintain the general nutrition by means of good food and tonics; of the latter the emulsion of cod liver oil with the lacto-phosphate of lime is probably the best. Good results have been claimed from a long-continued course of bichloride of mercury in minute doses, but I have had no experience with this method of treatment. Locally it is well to anoint the scalp with mercurial ointment, using oleate of mercury (50 per cent.) or compound iodine ointment. In applying these, the delicate condition of the skin must be borne in mind, and everything done to preserve the scalp intact by scrupulous cleanliness and occasional interruptions in the inunctions. Two plans of treatment have been suggested

neither of which have been very satisfactory in their results. The one consists in strapping the head, and the other in tapping the ventricles. In the first of these we must avoid making too much pressure. The hair should be shaved and the skin bathed with alcohol and water before each new application of the strap. Strips of ordinary rubber adhesive plaster one-half inch wide should be carried around the head from one occipital region to the corresponding temporal region, covering the whole of the cranium, and the ends fixed by a circular fillet. In performing the second operation, a fine trochar and canula should be inserted one-half inch to one side of the lateral angle of the anterior fontanelle. The fluid should be allowed to run until it stops of its own accord. No pressure nor aspiration should be made. The head should then be strapped to maintain the needed pressure. The parents should always be forewarned of the probable failure of the operation, for the fluid may reaccumulate rapidly, and also of the danger of convulsions and death.

Primary Dentition.

The advance of the two incisor teeth in the case I have shown you, have hinted to me that it would be well to occupy the remainder of this hour with a few remarks upon the subject of primary dentition.

You know that normally the human being cuts two sets of teeth, the primary or milk teeth—so-called from their whiteness—and the permanent teeth.

Primary dentition is usually performed between the fourth and thirtieth months. The teeth, in this set, are twenty in number, and are cut in groups, a period of rest occurring between the eruption of each group. The first teeth to appear are the two central incisors of the lower jaw usually at the sixth or seventh month, though at times as early as the fourth. Then there is an interval of from three to nine weeks followed by the eruption of the second group, the four incisors of the upper jaw, between the eighth and tenth months. This is followed by an interval of from six to twelve weeks, when the third group appears, the two lateral incisors of the lower jaw and the four first molars, between the twelfth and fifteenth months. After a rest of twelve weeks, the fourth group appear, the canine or eye and stomach teeth, between the eighteenth and twenty-fourth months, and this is followed by a period of from four to twelve weeks before the appearance of the fifth group, the four last teeth or posterior molars, by the thirtieth month.

The period of rest is a very necessary and important one. During dentition there is a disturbance of the whole system, and should all the teeth be cut at once the child would be made very ill. Therefore this period is required for recuperation.

The normal plan of eruption may be deviated from. The teeth may be cut too early. I have seen cases in which the first group of teeth was present at birth, while it is not unusual to see them by the fourth or fifth month. Nor is this an unfavorable circumstance, for an early dentition is usually an easy one. It is more apt to occur in children fed from the breast, and in girls than in boys. Next, dentition may be delayed, and the first teeth not appear until the eighth or ninth month, nor the last group before the third year. This delay in dentition should always bring up the question of rickets. It is more apt to occur in bottle-fed babies. Again the teeth may be cut irregularly, the groups not appearing in their normal sequence, or a number may appear at the same time. Delayed and irregular dentitions are both apt to be hard, and to give rise to certain symptoms of disease. The teeth most apt to give trouble are the third and fourth groups, but it is a fact that if one group causes a great deal of trouble, the remainder are apt to be cut without difficulty. The symptoms attending dentition are as follows: When you examine the jaws of a child in whom the teeth are not advancing you will observe that the gums are of pale pink color and have a well-marked ridge-like margin. When the teeth advance this ridge disappears, the gums become swollen, reddened, and moderately hot and tender to the touch. There is some increased salivation and the gum is the seat of moderate pain. These features of the normal process continue until the tooth pierces the mucous membrane, but are never so severe as to cause any disturbance to the child.

In difficult dentition all of these normal symptoms are exaggerated so that we may have catarrhal or apthous stomatitis, with pain, fever, loss of appetite, and general malaise. Other local conditions are ulceration on either side of the frænum linguæ from friction from the sharp edges of the lower incisors and profuse salivation. The latter condition is an important one for it may lead to so much wetting of the gar-

ments as to produce and maintain a severe bronchial catarrh, which, by the way, is apt to resist medical treatment unless the clothing be kept dry by a bib of oil silk or rubber cloth.

The general conditions attending difficult dentition are enlargement of the lymphatic glands at the angle of the jaw, certain eruptions upon the skin, especially eczema, strophulus, and urticaria; vomiting, diarrhœa, infantile convulsions, so-called dental paralysis—the latter being probably a condition of anterior polio-myelitis; blenorrhœa, and otorrhœa are also common complications.

Many authors have denied the connection of these symptoms with the eruption of the teeth, as they regard dentition as a physiological process and therefore incapable of inducing symptoms of disease. I think, however, there is an undoubted connection, for the interval between the fourth and thirtieth months of an infant's life—the period of primary dentition—is a year of great and widely distributed progress. Not only are the teeth advancing but the follicular apparatus of the stomach and intestinal canal is undergoing development in preparation for the digestion and absorption of mixed food, the cerebro-spinal system is rapidly growing and functionally very active, and the organs and tissues of the whole body are in a state of rapid change. This period of normal transition must also be one in which there is great susceptibility to disease, provided there be a causal influence at work. Such an influence may either originate outside of the body or come from within in the form of some physiological process. Difficult dentition in my mind stands prominent in the latter class.

Whichever of the above symptoms may be present, appropriate medical treatment is of course indicated, but I would especially call your attention to the propriety of lancing the gums over advancing teeth so as to thoroughly free them and do away with backward pressure and consequent irritation of the delicate nervous system. One should not wait until the gums are soft and swollen and until the edge of the tooth can be seen through the mucous membrane but should cut freely down, so as to divide the denser layers of gum and connective tissue whenever any of the complications I have mentioned are present, and examination of the gums shows advancing teeth. The operation is never properly performed unless the edge of the lancet can be felt to grate against the tooth. The incision over incisor teeth should be linear, over the canines rectangularly crucial, and over the molars obliquely crucial.

COMMUNICATIONS.

FLAP-SPLITTING IN PERINEORRHAPHY, WITH SPECIAL REFERENCE TO TAIT'S OPERATION.[1]

BY X. O. WERDER, M. D.,

PITTSBURGH, PA.

(*Continued from page 599.*)

The old method of Tait is described as follows, by Edis in his work on *Diseases of Women*, page 445:

"*Tait's Old Method.*—He (Lawson Tait) employs sharp-pointed scissors, running the point of the lower blade through the skin and mucous membrane (along the line c c c), to such a depth as will enable the operator to turn a flap backward from each edge of the rent into the rectum. In making this incision, it is important not to cut at right angles to the vaginal surface, but at a somewhat acute angle to it, so as to bevel the flap outward. The depth of the incision must also be so regulated as not to risk the life of the flap. When the raw surfaces are adjusted and fastened together, it will be seen that these everted flaps form a valve, uninterrupted by stitches, which closes from the rectum, and must, therefore, greatly aid the healing of the wound by preventing the admission of feces. To this peculiarity he attributes very largely the uniform success he has with this operation in a large number of cases. He uses no special needle: either a long-handled curved one, or a common curved needle in a needle-holder, threaded with some of Pearsall's pure silk, which he prefers to wire or silkworm gut. The upper stitch (1, Fig. 9) is first introduced. The needle may be passed from either side into the septum, about an inch from the apex of the rent, and its entrance and exit should always be just at the line of reflexion of the flap (*b b*). It is passed in the thickness of the septum and brought out within a quarter of an inch of the rent, entered again and passed similarly in the thickness of the septum and out again opposite its vaginal entry.

[1] Read before the meeting of American Association of Obstetricians and Gynecologists in Cincinnati, Sept., 1889.

If properly passed it should not, when tightened, be seen or felt either in the vagina or rectum, but should pass between the two mucous surfaces through its whole extent.

"The stitches are not to be tightened, however, until they have all been placed. If necessary, on account of the extent of the cut, a second, similar to the first, should be placed lower down (2). As a rule, one row with the perineal stitches will be enough; indeed, in very many cases the perineal stitches will do all that is required, and septal stitches are needed for bad cases only. The perineal stitch is then to be secured and then the posterior, the same precaution with the flaps being taken. The anterior stitches are then to be secured and the ends of all cut off, leaving about half an inch of thread. If the two edges of the incision do not lie quite close together, two or three superficial stitches had better be placed to bring them close."

That there is considerable difference between the operation just described and the new method of perineorrhaphy introduced to the public by Sänger, anybody can readily see by comparing the accompanying woodcuts. The difference consists not only in the formation of flaps, but particularly in the introduction of sutures. In the above operation the septum is stitched separately; in the new operation this is discarded entirely, all the stitches introduced being perineal. The new operation is, therefore, undoubtedly an improvement over the old one, not only in its remarkable simplicity of technique, but also in its results.

The patient to be operated on is prepared in the usual way, by the administration of

Fig. 9.

Tait's old method. Complete laceration of perineum.

The perineal stitches should never be less than three in number, and should usually be four. The third (5 in Fig. 9) should be introduced just within the line of the incision on a plane with the septum and its stitches, if there be any.

"All bleeding having been stopped and the wound thoroughly cleansed, the septal stitches are to be first secured, care being taken that the flaps are turned well into the rectum, and not caught in the tightened stitch—this being really the most important part of the operation. The middle peri-

laxatives for several days previous to operation and an enema on the morning of the operating day, or rather several hours before operation. The field of operation is shaved and thoroughly cleansed with soap and water, and then disinfected by a one to one thousand sublimate solution. I generally employ, during operation, irrigation of a one to four thousand bichloride solution, and in complete ruptures simple distilled or boiled water, or a weak solution of creolin. The legs are held in position by a Kelly leg-holder. The instruments necessary are a sharp-pointed scissors, preferably curved, a long Peaslee needle, an ordinary small curved needle and needle-holder for superficial sutures, one or two artery-forceps, and an equal number of tenacula, though the latter can easily be dispensed with. This is the whole instrumentarium necessary for this operation.

Tait's New Operation for Incomplete Ruptures of the Perineum.—It is well to introduce a tampon of iodoform gauze, with ligature attached, into the rectum, for the double purpose of causing bulging out of the posterior vaginal wall, and to prevent the escape of fecal matter during the operation. One or two fingers of the left hand are placed in the rectum in order to steady the vulvar and posterior vaginal wall, then the points of the scissors are inserted transversely (Fig. 10) midway between the

FIG. 10.[2]

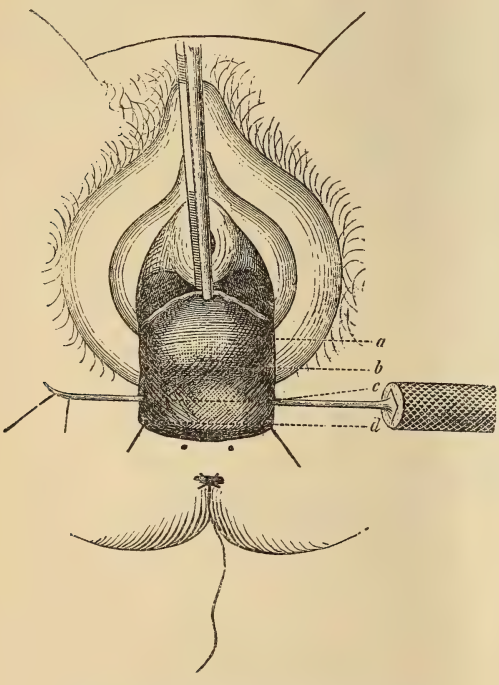
posterior commissure of the vagina and the anus as far as necessary, cutting first on the one side, then on the other side, undermining the whole cicatrix thoroughly to a point met by a straight line drawn from the external border of the juncture of the small and large labia (Fig. 10, *a*). Turning the scissors then from the horizontal to the vertical position (*a b*, Fig. 10), the incision is prolonged along the left labium majus to the point at which we intend to form the posterior commissure, usually a little external to the lower border of the nymphæ (*b*). The same incision is repeated on the other side. The whole flap, which now presents a rectangular outline, is loosened and raised up by a tenaculum or the finger. The flap, when completely dissected off, loses its angular form and shrinks considerably, assuming an oval shape. It is lined by skin all around taken below from perineum, and on the sides from labia majora, except, of course, at its seat of attachment, where it is continuous with the vaginal mucous membrane. The bleeding is usually not considerable, and easily controlled by irrigation with hot water; sometimes, however, it is necessary to grasp a few small arteries with the forceps and twist them. Ligatures are very rarely required.

Fig. 11.

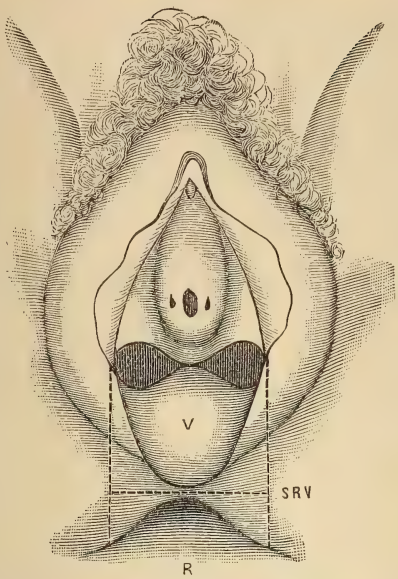


Method of inserting sutures.—(Taken from Sänger.)

In regard to suturing material I have followed Sänger, who uses silver wire for the deep and silkworm gut for the superficial sutures. Tait himself, it is said, also Mundé and others, uses silkworm gut for all the sutures, others again, prominently Martin, of Berlin, unite the whole raw surface with rows of buried catgut sutures. With one or two fingers in the rectum, a Peaslee needle is inserted about an eighth of an inch from the left border of the wound, and carried under the whole raw surface, bringing it out on a corresponding point on the opposite side (Fig. 11). The silver wire is then passed through the eye of the needle and the latter withdrawn. The wire is not tightened until all the deep sutures are placed. Care must be taken that all the sutures are buried, but do not penetrate either the vagina or the rectum. One suture should pass behind the recto-vaginal juncture—*i.e.*, the place where the flap is attached to the rectum. More than three or four deep sutures are rarely needed. When the stitches are tightened it will be found that the edges of the skin come together very nicely; when this is not the case, however, they are brought into contact by some superficial sutures. One or two superficial sutures are nearly always required at the new posterior commissure of the vagina, where there is apt to be a little gaping. The superficial sutures are cut short but the deep ones I am in the habit of leaving long, as they serve to hold the dressing in position. The wound is now washed off again with the antiseptic solution, dusted with iodoform, and covered with a layer of absorbent cotton.

Operation for Complete Rupture of the Perineum.—Here the operation differs very little from that just described. The torn recto-vaginal septum is carefully divided transversely by scissors to a vertical line, drawn from a little outside the juncture of the large and small labia (Fig. 12, S R V; Fig 13, A A, and A B and A B); the incision is then extended up along the labia majora on each side. The vaginal being now finished, the rectal flap is made by carrying the incision downward to each side of the anus (Fig, 13, A B and A B), just outside of the stumps of the sphincter muscle (Fig. 13, C). The whole incision resembles the letter H. Now raising up the vaginal flaps with a tenaculum, and turning down the rectal flaps

Fig. 12.



Tait's new operation for complete rupture of perineum, taken from Sänger.

into the lumen of the rectum (Fig. 14), the raw surfaces will be found in such close contact as if stitched together. The sutures are introduced in exactly the same manner as previously described (Fig. 14, S S S S), but it is very important that the last suture

should pass through the torn ends of the sphincter ani muscles (Fig. 14, S B, S B).

The bowels are moved on the third day by a laxative, and unless regular, the laxative is repeated every other day. Only liquid diet is allowed the first few days. Instead of catheterizing the patient I have lately been in the habit of introducing a permanent catheter immediately after operation, consisting of a Skene-Goodman catheter, to which is attached a rubber tube two to three feet long, closed by a stop-cock. This is very convenient when the operation is performed in the patient's house and when no trained nurse is at hand. Even

in hospital practice I have found the permanent catheter of great advantage, as it saves the patient and the attendant much annoyance and, if made perfectly aseptic, there is less danger from cystitis. It does not give the patient any inconvenience whatever; in fact, it was left in the bladder in one case for seven days by mistake without causing the slightest trouble.

The after-treatment consists in changing the dressing of absorbent cotton whenever it becomes soiled, blowing some iodoform on the wound each time. The wound should be irrigated after every motion from bowels

or bladder. Vaginal injections are not necessary. The pain is usually very slight and anodynes are rarely required. The superficial sutures are removed on the eighth day and the silver wire on the fourteenth day. Sänger removes all sutures now on the twelfth day and allows the patient to leave the bed. The wound is generally perfectly healed at that time. Occasionally there is a small granular surface at the seat of the wire sutures, which, after they are removed, heals in a few days. In two of my cases a small recto-perineal fistula formed. The first case had uterine prolapse, with cystocele and recto-vaginal fistula, there having been a rupture of the recto-vaginal septum and perineal muscles, leaving, however, the perineal skin intact. An operation for closing the perineal laceration had been done fifteen years ago, leaving a recto-vaginal fistula which had remained open ever since. I amputated the cervix, made an anterior colporrhaphy, using buried catgut sutures, closed the recto-vaginal fistula with catgut and restored the perineum by Tait's method, all at one sitting. Her bowels were moved on the fourth day by a laxative. On the sixth day she had great tenesmus, sitting on the bed-pan all day without being able to pass anything. When I saw her late in the evening I found a large, hard mass in the rectum which I had to break up with my hand. In washing out her rectum I noticed that some of the water was escaping through the perineal wound. The recto-vaginal fistula had evidently re-opened through her straining and permitted water and fluid feces to pass through. This fistula closed up, however, in a short time, and the result of the operation was very satisfactory.

The second case was an extremely unfavorable one for operation. There was not only a rent extending from two to three inches up into the rectum, but the rectum was prolapsed, protruding about two inches when the patient was in the horizontal position, but when on her feet or in the act of defecation it came down certainly six or seven inches. The rupture had existed for at least fifteen years, and during the last six months locomotion had almost become impossible. In order to make the flaps sufficiently large to cover the defect and to prevent their sloughing, the incisions were made very deep both up the vagina and into the buttocks. In this case a recto-perineal fistula formed because one of the silver wire sutures, of which there were seven, broke. Though at the last examination, about two months after the operation, there was still a small fistula present, it had contracted so that no fecal matter escaped through it. In order to retain the bowel and to secure it against prolapse, after returning the bowel to its normal position, I passed one of the silver sutures through the external coat of the rectum. The patient has almost complete control of her bowel now and there is not the slightest tendency to prolapse. Physically the patient is now perfectly well, but her mind, which was slightly unbalanced before the operation (due, as we thought, to her wretched condition), is now entirely deranged, so that her transfer to an insane asylum became necessary.

In my first operation I followed Sänger's advice to insert the sutures exactly at the edge of the wound, but within the wound surface. But I have found that when the sutures were tied the skin borders became slightly separated, requiring a number of superficial sutures to keep them coaptated. In the subsequent cases, therefore, I inserted the needle just within the skin, about one-eighth inch outside of the borders of the wound, thereby causing more accurate coaptation of the wound surfaces. If too much skin is caught within the stitches, it is apt to roll in, thereby preventing primary union.

In regard to the depth of the incision no definite rule can be given. In perineorrhaphy for incomplete rupture the flap does not need to be thick and fleshy, one-eighth to one-fourth inch being certainly sufficient. This will suffice also for the ordinary complete rents through the sphincter ani, but in cases of very deep tears extending high up into the rectum, such as the case just described, the dissection must reach a considerable distance above the rectal rent and into the buttocks, as we need a large, thick and bloody flap, one that will not only be able to cover the very extensive defect but which will live and not become gangrenous.

My experience with this operation has been extremely satisfactory, though limited to eight cases. Three of these cases were complete lacerations, all of them healing by first intention except the one described in which a small recto-perineal fistula remained, now rapidly closing up, however. The results have been perfect in each case, as also in five cases with incomplete ruptures. One of these was complicated with recto-vaginal fistula of long standing, which I sewed up

with catgut before performing Tait's operation. Zweifel and Sänger each report one case of fistula, for which no extra treatment was used, and both of which were cured permanently by Tait's operation for the repair of the perineum. In one case I amputated the cervix and performed anterior colporrhaphy at the same sitting. In two cases I performed trachelorrhaphy and in one trachelorrhaphy and curettement of the uterus.

Sänger reported at the last meeting of the German Society of Gynecology, at Freiburg, seventy-one operations performed according to this method, ten of which were complete ruptures, none of which failed. Howard A. Kelly closed up a complete rent which had been operated ten times unsuccessfully, by Tait's new method with an excellent result. P. F. Mundé operated seventeen times, eight complete and nine incomplete ruptures, with a perfect cure in each case, except one, which, strange to say, died from septicemia. In the *British Gynecological Journal*, August, 1889, Fancourt Barnes gave a complete history of twelve cases of complete laceration of the perineum operated on by Tait's new method, in all of which perfect cures were obtained. I might add the reports of many other operators, but I think this list will be sufficient to convince the most inveterate sceptic of the efficiency of the operation.

There is certainly no operation that can compare with this in simplicity, celerity of performance, and uniform success. For complete ruptures I regard it as the ideal method which, in my opinion, is destined to rapidly supersede the old triangular operations which so often fail. In this operation the success does not depend, as in the triangular methods, on the behavior of the sutured vaginal and rectal mucous membrane; but, to use Sänger's words, "on the rapid, certain, and firm cicatrization of the perineal skin." The occurrence of recto-vaginal fistulæ, so common after the older methods, seems impossible after this operation. Should primary union of the perineal wound fail to take place at certain points, this will not mar the success of the operation, as, especially when the posterior vaginal commissure and the sphincter ani muscles have united, secondary union will always take place. Even a total failure would at least not increase the trouble, as no tissue has been removed, and the parts simply remain *in statu quo*.

MEMBRANOUS CROUP AND DIPHTHERIA.

BY P. J. FARNSWORTH, M. D.,
CLINTON, IOWA.

Charlie W., seven years old, came home from school complaining of symptoms of a common cold; coughing a little as if from bronchitis, but saying nothing of sore throat. Ate his supper and after a little time went to bed, his mother getting him warm and tucking him carefully in. About three in the morning the parents were aroused by the cries and brassy cough of the child. The mother suspected croup, and put a cloth wrung out of cold water around the neck and made some hot tea of summer savory, which he drank, also taking a half teaspoonful of *Hive* syrup (*Tr. scilla, Com.*), which produced vomiting and relieved the paroxysm, and he fell asleep. At nine or ten in the morning he had an attack of coughing of the same croupy character and again at intervals during the day. At night soon after going to bed, he roused up with the same brassy cough and considerable dyspnœa. I was called at once, and found the boy in a high fever, but breathing without much difficulty, and somewhat hoarse. I examined the lungs, but did not find any serious râles or crepitation. Examination of the throat only revealed a little irritation. Waiting a little before prescribing, all at once the peculiar brassy ringing cough came on and considerable spasm of the glottis was noted. It was unmistakably membranous croup. An emetic of ipecac relieved the paroxysm, ice cloths were applied to the neck and inhalations of steam from an atomizer used.

There was no prostration and the fever soon subsided. A solution of potassa iodide was given in doses of ten grains every two hours. The paroxysms increased and by the next night breathing was labored, the cough more frequent, the voice nearly lost; still no membrane could be discovered in throat. With the assistance of a neighboring practitioner we introduced a tube into the larynx. The boy was docile and assisted us as much as possible and the tube was placed without much difficulty. It relieved the breathing for a little time, then seemed to add to the distressing symptoms and was removed. Stimulants were then tried, but no great amount was taken. Dilute alcohol was given in spray form. Cal-

omel in five grain doses every two hours had been given. It was all to no purpose, and towards morning of the third night breathing became so labored that it finally stopped. We did not try tracheotomy, and could not get a *post mortem*.

Several physicians were called in to see the case. Some of them had never seen one like it. Some of the older ones called it membranous croup at once. Several were attending cases of diphtheria and had often seen cases of diphtheritic croup, but none with symptoms like this.

It did not become a constitutional disease, nor was it so at first. It began in the larynx; membrane did not make its appearance in the fauces. There was no great amount of fever except when the paroxysm was on; there were intervals of what seemed to the casual observer total abatement of the disease. The cough appeared suddenly and with the true croupy ring, which if once heard is never forgotten. There was no affection of the lymphatics. It may be said that there was not time, but in croupous-diphtheria the lymphatics are invariably enlarged, and there are other signs of septicemic poisoning. There was no fetor of breath, which is characteristic of diphtheria. Without enumerating the negative symptoms of diphtheria, which was prevailing in another part of the town, the difference was so marked that all who saw the case declared at once that no mistake could be made in the two diseases.

Membranous croup is not a common disease. No genuine cases have been observed in this locality for six years, and then only one or two cases were reported. Physicians of twenty years' practice stated that they had never seen a genuine case before. For this reason, the rarity of the disease, so many practitioners declare the diseases identical, when probably they have never seen a case of genuine membranous croup.

In 1860, being a student in New York, I saw several cases of well-marked diphtheria, just then beginning to prevail. Observed it well and listened to lectures on the subject. In the second year of my practice I saw four cases of membranous croup; three of them died. The next year we had many cases of diphtheria of which only one died out of twenty. Since then I have passed through some severe epidemics of diphtheria, in one of which forty cases were fatal out of a hundred. Of genuine croup I have not seen more than ten cases in twenty-five years, since the second year of practice. It seems less frequent than formerly. In some of the records of the old practitioners, say during the first half of this century, cases of membranous croup were numerous and the disease seemed epidemic; these cases may have had diphtheria, but the descriptions are so clear, that it seems hardly possible. Diphtheria undoubtedly did occasionally occur, for as early as 1680 a New England clergyman speaks of a malignant sore throat that prevailed at the time that is described in many of the terms of diphtheria, and at several other later periods it was described but disappeared again, so that up to about 1858 old practitioners had never seen the disease. Since then there are few, unfortunately, that are not familiar with it.

Membranous croup is confined to children, and the percentage of death is very large; eighty per cent. or five out of six die, under any treatment yet devised. Inhalations afford relief, and lime water dissolves the membrane. Mercurials, theoretically, should arrest the disease, but time is seldom given for the drug to get its full effect. Tartrate of antimony is worse than useless, and emetics only occasionally dislodge the membrane. Tracheotomy is sometimes successful; intubation has promised relief, but is of doubtful utility.

A case occurred in my own family in which a large amount of gin seemed to be the remedy. The little one was three years old, and had been incautiously exposed to the winds of March, with insufficient clothing on. In the night we were aroused with the dreaded cough. It might be pseudo-membranous, so an emetic was given, which gave temporary relief, but with day the fearful ringing sound was heard and the paroxysms increased towards night. A perusal of the literature on the subject is a meditation on death, and, in previous experience, all the routine remedies had been tried without success. Iodide of potash suggested itself, from its effect on spasmodic asthma, and seemed to give some relief. There was considerable depression of the heart's action at times and some alcoholic stimulant was prepared, which happened to be some cordial gin having a pleasant bland taste. An ounce or more was reduced with an equal amount of water and simple syrup, with directions to give a teaspoonful occasionally. The child was thirsty, and the mother mistaking the grog for water gave the child an ounce of the mixture. Relaxation

seemed immediately to take place, the paroxysms of coughing seemed softened, and the breathing relieved. More of the remedy was given, and evident signs of alcoholic intoxication were soon apparent, which were kept up for three or four hours by all of the drink the child would take, which amounted to as much as three ounces of the compound. An emetic was then given, and the membrane came up in long shreds with the superabundant alcohol. Sleep followed at once, with easy breathing, and a speedy recovery with little apparent prostration followed. That was six years ago, and the one described in the first part of this paper is the next one that has occurred in my practice. In the last case the iodide seemed at first to mitigate the disease, but the mercurial that followed produced no effect, and it was impossible to induce the child to take alcohol enough in any form to produce its impression.

The alcohol treatment has been tried with some success in diphtheria, with patients that were more manageable than children, and there is some hope that it may prove efficacious in certain cases of that disease. In diphtheria the fatal issue is produced by heart failure, exhaustion, paralysis and by suffocation, and stimulants may avert some of these symptoms. In croup they die, as a rule, from suffocation.

Society Reports.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated Meeting, October 3, 1889.

Dr. Theophilus Parvin in the Chair.

Dr. E. P. Bernardy reported a case of

Post-Puerperal Hematocele,

for which he operated successfully. The patient was thirty-eight years old. Four days after a normal, but somewhat tedious, labor, the patient complained of a sense of fulness of the abdomen. She also had constipation, and could not pass her urine. Examination by the rectum showed a tumor about the size of an egg, and vaginal examination revealed a tumor behind and to the left of the uterus. The tumor rapidly enlarged, and in a week filled the entire rectal cavity, pushing down to almost the external sphincter. The entire left side of the pelvis was completely filled by the growth, which pushed the enlarged uterus well to the right side, making it appear as if there were another tumor. Operation was advised and was performed five days later. The usual medium abdominal incision was made; on introduction of the finger in the abdomen, the entire left side of the pelvis behind the uterus and broad ligament was found filled by a tumor which was surrounded by adhesions which were readily separated before enucleation. In passing the finger behind the right side of the uterus, the finger ruptured some slight adhesions, entering a cavity from which freely flowed thick blood, looking and smelling like blood contained in an extra-uterine sac. After enucleating the left-side tumor, an immense cavity was left, which was, as well as the abdominal cavity, well douched with hot water; both ovaries and tubes were healthy, and were not touched; a glass drainage-tube was introduced, and the abdomen closed. On the sixth day, glass drainage-tube changed for a rubber-tube. Three days later this tube was taken out and the stitches taken out the sixth day. Eighteen days after the operation the wound had entirely healed up, and the patient soon after was allowed to go home.

Dr. H. H. Kynett reported a case of double pyosalpinx and double ovarian abscesses; a case of double hydrosalphinx and left ovarian cyst, and lastly a case of tumor of the breast, which he believed to be a milk cyst. All three cases were operated upon successfully.

Dr. W. L. Taylor then read a paper on the removal of a large

Ovarian Cyst,

followed by rupture of the right common iliac vein. The patient was twenty-four years old, and very much emaciated; her abdomen enormously extended. A lump had appeared in the right side of abdomen about two years ago which never caused any pain, but only a sense of discomfort from pressure, and with rapid increase in size.

Upon examination, the abdomen gave evidence of the presence of a very large encysted fluid, ovarian in character. On July 7, Dr. Taylor operated and removed a non-adherent cyst of the right ovary. The fluid of the cyst was syrupy and very heavy, weighing fully fifty pounds. The pedicle

was unusually thick and was tied in sections, and finally with a Tait ligature. The steps of the operation were devoid of special interest, and but little cyst fluid or blood escaped into the abdominal cavity. The latter was thoroughly washed out, and the absence of bleeding-points was remarked. Noticing a slight oozing of blood from the region of the pedicle, the operator investigated, and found that a couple of veins, which were greatly distended, had ruptured just beneath his ligatures. These were tied securely, and whilst doing this he noticed higher up—fully as high as the sacro-iliac juncture, and to the right side—what appeared like an adherent intestine, rapidly distending, with a central portion most distended. This rapidly thinned out, and gave every appearance of speedy rupture. Touching it gently with his finger, it burst instantly, and there was a frightful gush of blood. The bleeding vein, for such it proved to be, was quickly grasped and then caught with a large Pean forceps, which imperfectly controlled the hemorrhage. Then the vein was separated from its artery and ligatures carried securely around it. These immediately stopped all hemorrhage, but caused a very decided and alarming venous swelling on either side of the ligatures. The wound was then closed up after introducing a drainage-tube. At the close of the operation, the patient's pulse was 160, the temperature sub-normal, and the respiration about 40. Everything certainly pointed to a positive recurrence of hemorrhage, and she was most carefully watched.

In the discussion which followed,

Dr. William Goodell said that this seemed to be an unique case. He had never seen anything like it in simple unadherent cysts. In intraligamentary cysts he had often torn deep-seated veins, and had had difficulty in checking the hemorrhage.

Dr. J. Price said that he thought that there was great danger of wounding the vein by the use of the Baker, Brown or Peaslee needle. These accidents have occurred from traumatism, from manipulation, and wounds made by the use of instruments.

Dr. W. L. Taylor said that the hemorrhage occurred long after any traumatism could have happened, and was so much higher than the pedicle, that he thought it could not be attributed to traumatism. The hemorrhage was spontaneous. It did not occur gradually, but there was a sudden gush of blood following the touch of his finger.

Dr. Theophilus Parvin then read a report of a case of

Tubal Pregnancy,

probable diagnosis, and removal prior to rupture.

This patient was brought to the hospital of Jefferson Medical College, September 19, suffering from a probable ectopic gestation. Upon examination, Dr. Parvin found a tumor adjacent to the uterus upon the left side, the uterus was somewhat enlarged, and very sensitive to pressure, as was also the vagina and the lower part of the abdomen. The history, the examination, and the previous examinations of Dr. Baldy, with his conclusion, left but little doubt that the case was one of tubal pregnancy. Abdominal section was done on the 20th of September, Dr. Baldy and Dr. W. E. Ashton assisting in the operation. The gestation cyst included in the tube was removed. The patient's convalescence has been uninterrupted.

Dr. J. M. Baldy reported a case of

Tubal Pregnancy, no Diagnosis, but Removal Prior to Rupture.

The patient (colored) had walked into the out-patient clinic of the Howard Hospital, July 5, 1889, suffering from pain in her abdomen, so similar to that which I have often seen go with a pyosalpinx, that I diagnosed this disease before examining her. The examination revealed a large, apparently tortuous, tender mass, posterior and slightly to the left side, giving a boggy feel to the touch. The diagnosis was verified, a saline purge given, and an immediate operation advised.

One week later, a messenger summoned me to the home of the patient, where I found her lying on the bed, suffering from severe pain in the abdomen. A reëxamination of the pelvis showed only what had been before found; viz., a cystic mass, which did not pulsate, posterior and to the left; apparently a distended tube. The uterus was in position of normal anteflexion, and there was a perfectly normal cervix for a multipara. There was an elevation of temperature, and the woman had had chills. It was decided that it was a case of pyosalpinx, at the same time ectopic gestation was thought a possibility, but sufficient data on which to verify this suspicion were not found. The abdomen was opened the next day with the

assistance of Drs. Hamill and Naylor, and a left tubal pregnancy removed. The case well illustrates the difficulty, nay impossibility, of at times diagnosing ectopic gestation. In three weeks the patient was sent home and is to-day in her usual good health.

Dr. E. W. Cushing, of Boston, said that the subject of extra-uterine pregnancy is one of great interest to him, and he could say, from sad experience, that it is not easy to make a diagnosis. After some obscure symptoms of irregularity of menstruation, etc., a near relative was taken suddenly with a severe attack which, after the event, he felt was due to a tubal pregnancy ruptured into the broad ligament; she finally recovered without operation. In another case a physician operated for an ill-defined tumor. The cyst was opened after the operation, and a fetus three-fourths of an inch in length found. There had not been a suspicion of pregnancy.

Dr. William Goodell said that in regard to the electrical treatment of extra-uterine fetation, he was theoretically inclined to believe in it. But when he had met with cases of extra-uterine fetation, and saw the mass that was present, and the adhesions and injuries which adjacent organs had sustained, he could no longer uphold it. He had practically been converted to the belief that electricity, and particularly electrolysis, should not be used in these cases. The electrolytic action is a most dangerous one. Although advocated by Apostoli, the results have been most disastrous in the cases in which it has been tried. He had had four cases of early extra-uterine pregnancy within a few months, all of which were successful. He believed that Tait was correct in explaining advanced cases by the rupture of the tube and the escape of the unbroken gestation sac into the fold of the broad ligament. The behavior subsequently is precisely like that of an intraligamentary ovarian cyst.

In regard to early diagnosis, he should say that the most common symptom is arrest of menstruation for one or two periods, followed by irregular uterine hemorrhages. It is true that pelvic colic is a common symptom, but not so common as the other.

Dr. Barton C. Hirst said that some time ago he was called to a case in consultation which presented a clear history of extra-uterine fetation; cessation of two periods, hemorrhage with the discharge of deciduous membrane; a distinct tumor to one side of the uterus, and the subjective signs of pregnancy, with swelling of the breasts and vomiting. Dr. Hamill and myself urged operation, but the family being dissatisfied, we were discharged. Another physician was called, and Dr. Parrish was consulted. He recommended the use of electricity, and a current was applied with relief of the symptoms, and complete cure of the patient. There might have been a varicose vein in the broad ligament which having burst may present all the signs of extra-uterine fetation after rupture of the sac.

Dr. M. Price had seen twenty or twenty-five cases of extra-uterine pregnancy, nearly all of them ruptured tubal pregnancies. It does not interest us a particle whether the cases were diagnosed or not. There is trouble present of such a serious character that it does not become us to lose a single moment. Most of these cases come into the coroner's and not the surgeon's hands. Delay in operating is adding ten per cent. to our mortality. It is our duty to operate on the first indication, and if we are mistaken, to thank God for the absence of so serious a condition.

Dr. Joseph Hoffmann had twice operated for extra-uterine pregnancy and did not find it, and had operated for something else and found extra-uterine pregnancy. The first case presented the signs of extra-uterine pregnancy to even a more marked degree than that of Dr. Hirst,—coming on after a sterility of eight years, a retroverted mass, flooding and violent pain. At the operation he found two pus-tubes. In the third case he operated for pus-tube and found extra-uterine pregnancy.

Dr. Noble said that a short time ago he removed an extra-uterine pregnancy which was rather unusual in the conditions present (see Medical and Surgical Reporter, November 16, 1889). The patient was seen by Dr. Kelly, and it was agreed that it was almost certainly an extra-uterine pregnancy.

Dr. B. F. Baer said that he wished to go on record as one who believed that it is as easy to diagnose extra-uterine pregnancy as to diagnose any other condition within the abdomen (as hydrosalpinx or pyosalpinx) positively.

In Germany the Government has come to the conclusion that there are enough medical colleges in the country and refuses to allow any more to be organized.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Stated Meeting, October 23, 1889.

The Vice-President, JOHN B. ROBERTS, M.D., in the Chair.

DR. JOHN B. ROBERTS presented a paper entitled

Extraction of Cataract.

In giving a brief outline of the steps of the operation, Dr. Roberts said that in preparing the patient for operation, he cleanses the face in the vicinity of the eyes with soap and water, and subsequently with a solution of boric acid or corrosive sublimate. He then washes out the conjunctival sac with a boric acid solution instilled with an ordinary pipette. A few drops of four per cent. solution of hydrochlorate of cocaine is dropped into the eye two or three times during the quarter hour preceding the operation. A few drops of a four-grain solution of atropia is also instilled. The steps of the operation are as follows: Having grasped the conjunctiva and the inferior rectus with a pair of fixation forceps, an upward incision of the cornea is made with a Graefe, Beer, or Jackson knife.

The iridectomy is accomplished by catching and drawing out the iris with an iridectomy hook in the left hand, and cutting it with the Levis spring scissors in the right hand. He does not use the iris forceps for the iridectomy unless it happens that, for some reason, a portion of the part excised has not been perfectly detached from the iris. He then uses the forceps to catch the ragged edges while making a second attempt at complete division. Laceration of the capsule is done by making a T-shaped incision with a cystotome. The lens is then extruded by pressure upon the sclerotic and cornea, with the finger above and a tortoise-shell scoop below the incision. The finger makes the pressure from the outside of the upper lid. If there is any difficulty, as there often is, in evacuating the soft cortical material or nucleus, the spoon is introduced and the remnants extracted. After a few minutes have elapsed to allow reaccumulation of the aqueous humor, the patient is allowed to sit up with his back to the light, and a convex lens of about nine dioptrics is placed before the eye which has been operated upon in order that the patient may be convinced that vision has been restored.

After instilling a few drops of atropia solution the eye is sealed by means of two or three small strips of ordinary rubber plaster upon the upper lid. These strips of plaster are cut in the shape of a semi-ellipse, and are made to fit the upper lid, but under no circumstances are they to overlap the lower lid. In this manner the upper lid is made stiff and acts as a splint to the wounded cornea.

The advantage of this method is that the eye is not heated, and tears and mucus can drain from between the eyelids, and atropia solution can be introduced into the conjunctival sac every morning or evening, as the surgeon may deem proper. Before the operation it is best to cut off the eye-lashes of the upper and lower lids, to prevent the eye becoming sealed by dried secretion upon the lashes, which gives the patient pain, and has a deleterious effect upon the eye by interfering with the free flow of tears and mucus. As a rule, only the eye which has been operated upon is closed, and the patient is not restricted to a dark room, or confined to bed.

In the discussion,

DR. GEORGE C. HARLAND said, that the points of most interest at the present time, in connection with this operation, are: the after-treatment, the use of antiseptics, and the performance or non-performance of iridectomy. There is no doubt that the after-treatment has been much modified of late. The patients are not kept so long in bed, and the dressings are much simpler. He thinks it well to use the bandage for two days, and to keep the patient in bed two or three days. As boric acid has been shown to be without antiseptic qualities, he has abandoned it, and now uses bichloride solution, 1 : 5000. Even in this proportion it causes some irritation of the conjunctiva. The question of iridectomy is now the great point of discussion. There is a strong party in favor of omitting iridectomy in the operation for cataract. There are æsthetic and perhaps optical considerations in favor of a round pupil; but this advantage, which has been somewhat exaggerated, is dearly bought at the expense of the greater difficulty in accomplishing delivery of the lens and the removal of cortical *débris*, and particularly of the risk of prolapse of the iris. Alfred Graefe, at last year's meeting of the Heidelberg

Society, said that he had allowed himself to be bewitched by the round pupil, but that prolapse of the iris had disenchanted him.

Dr. B. Alex. Randall said that he had thus far done iridectomy in all operations, as it facilitates egress of the lens. A small removal of tissue is generally sufficient; and, after it, he has secured a perfectly mobile pupil, almost as round and perfect for visual purposes as though no iridectomy had been done—the coloboma being thoroughly covered by the upper lid. Dr. Randall emphasized the point that cocaine must be used with caution, since it affects the nutrition of the corneal epithelium: and our studies show that it is largely upon this epithelium that the healing process depends.

Dr. Mordecai Price then read a paper on

Ectopic Gestation.

He said, in order that ectopic gestation may be possible, the tube must be diseased, its lining membrane removed, its ciliated epithelium no longer urging the product of conception onward to its natural abiding-place nor retarding in the least the spermatozoa from intruding on dangerous and forbidden ground. This condition is brought about, he believed, in fifty per cent. of the cases by gonorrhœa, and the remainder by cold, and septic conditions following childbed and catarrhal affections from other causes. That the pregnancy in the beginning is always tubal is well proven, from the fact that the tube is the only portion outside the uterine cavity offering the conditions favorable for impregnation. The product of conception thrown into the peritoneal cavity either at the time of impregnation or during the first few weeks of gestation would undoubtedly be digested. We have the best proof of this in the fact that in early ruptures into the peritoneum of only a few weeks, no fetus can be found; only the blood clot, the diseased tube and membrane remaining. Those cases that have advanced to maturity in the peritoneal cavity have without doubt been those first developed in the tube, and then ruptured in the broad ligament, and when able to resist the digestive fluids of the peritoneum, the secondary rupture has taken place.

Tubal pregnancy would be of but little moment to us, if it were not for the fact that most patients are not aware there is anything wrong. If they suspect pregnancy at all they have no reason to doubt that it is the usual old-fashioned kind, and the first warning, alike to patient and doctor, is rupture of the tube, with symptoms of internal hemorrhage—often so serious that the patient lives but a few hours. These cases are far more numerous than is supposed—in this city alone about twenty-five a year. Five years ago the mortality was one hundred per cent., and now at least ninety per cent. are saved. The symptoms of ectopic gestation before rupture are of a vague and uncertain character.

In most cases of ectopic gestation in his own hands, the diagnosis was made before operation. Rupture had taken place in every case. Diagnosis of tubal pregnancy before rupture would simply be a happy guess.

In the discussion which followed,

Dr. A. J. Downes said that while in Atlantic City, a year ago, he was hastily called to see a woman in collapse. There was great abdominal pain. She had had two attacks of pain and collapse on the day before he saw her. At 10 A. M., she had another attack, and at 11 o'clock he saw her. In the afternoon she had a fourth attack and died. The point he wished to raise was, whether after the third collapse, with the abdomen filled with blood, a surgeon could go in without trained assistants, with a prospect of relieving the patient.

Dr. James Collins remarked that in an emergency, a surgeon who knows his anatomy, who knows how to tie a knot and keep his head level, is justified in doing anything. He should stop the bleeding if he is sure of his diagnosis.

Dr. J. Hoffman said that it was unfortunate that some of the advocates of early diagnosis were not present. A case has recently been reported where it was claimed that a five months' fetus was melted away. Such a thing as that is impossible. He had twice operated expecting to find extra-uterine pregnancy, but failed to find it. Once when operating for something else he did find it.

Dr. J. Price said that the course of surgeons in the treatment of this condition is well grounded. It is our duty in cases of hemorrhage to seek the offending vessel and secure it.

The diagnosis of early tubal pregnancy cannot be made from the physical signs. The history and symptoms with the physical signs often make it highly probable that we have to deal with ectopic gestation, but that is about all that we can say.

PERISCOPE.

Removal of Plaster of Paris Dressing.

Dr. Charles H. Richardson, of New York, describes, in the *Medical Record*, November 16, 1889, a way of removing plaster dressings as follows: I have used of late a plan in the removal of plaster and starch bandages which seems to do away with the annoyance to the surgeon, and the discomfort, not to say distress, to the patient, attending removal by the shears. It consists simply in the application of a piece of wire under the bandage, which is made to cut its way out when removal of the apparatus is desired. The limb is prepared for the bandage in the usual manner, either by the application of a flannel roller or by being well anointed with vaseline. A fine steel wire is then laid the length of the limb, in the situation that it is desired subsequently to cut, and firmly held in that position by an assistant. This is secured by a few turns of the plaster bandage, and the apparatus finished in the ordinary way. The wire should project four or five inches at each end of the bandage, so as to afford sufficient for a firm hold when the time comes for removal. These free ends of wire may be bent down after the casing is completed, to prevent the annoyance to the patient which the sharp ends might otherwise produce.

When the removal of the appliance is desired it is necessary to have the patient rest his limb on a table in order that it may be perfectly steady, and while the lower projecting end of wire is held firmly in place, to prevent its slipping underneath the bandage, the upper end is seized by a pair of pincers and by firm traction made to cut its way through the whole length of the casing. The apparatus may now be bent back and removed, the operation having caused no discomfort, which can hardly be said of the combined prying and cutting with a pair of plaster shears.

He calls attention to two points: the first is that no attempt should be made to remove the casing until it is completely and entirely dry, as the wire will not cut through wet bandage. The second is, that while one wire will cut through the ordinary light dressing, such as is used on the arm, yet when an extra thickjness is given to the apparatus, as in a plaster acket or in an appliance to the lower limbs, I would recommend that two or even three wires be used, to make the cutting easier and more sure. If more than one wire be used, the second is laid as nearly over the first as possible, after a few layers of bandage have been applied, and a third over this if it be deemed necessary. Thus a layer of plaster and bandage will intervene between each of the two or three wires. The method of cutting is evident. It is done in sections, by pulling the wires in inverse order to that in which they were laid.

Intussusception at Three Years of Age, Successfully Treated by Rectal Injection.

Dr. John W. Farlow reports in the *Boston Medical and Surgical Journal*, November 4, 1889, the following instructive case.

N. R., a three-year-old boy, had always been well, I saw him March 7, with the story of having been somewhat under the weather. His mother had given him castor oil, which produced four or five loose stools. I saw him in the morning, and found him crying at intervals and putting his hand near his umbilicus. The anus was rather relaxed and he passed a little blood and slime from time to time. Nothing was felt in the abdomen. At 4 P. M. the pain had increased and was paroxysmal; at 9 P. M. the same condition, only more pain. The next morning early I found that he had slept some in the night, but since six o'clock he had cried and thrown himself round on the bed and over on to his face. He still passed blood and slime, but no feces. He kept putting his hands near the umbilicus and said the pain was all there. To the left of the umbilicus a very marked fulness could be seen, the lower part of which was dull and rather firm, while the upper part was tympanitic. The diagnosis seemed assured.

The boy was inverted and his feet held up high. By means of a Davidson's syringe I injected slowly into his rectum one and one-half pints of luke-warm water, at the same time trying to press back the tumor from the outside. The child only cried the harder. About fifteen minutes later he got up and passed the water. Nothing but a little blood came with it, but on getting back to bed he stopped crying, and from that moment the pain entirely ceased and the tumor was no longer felt. The case was uneventful after that. He had a fair stool

March 11, three days after the intussusception was reduced. I have seen him several times since, and he continues in good health.

Foreign Body in the Trachea.

In the *Virginia Medical Monthly*, November, 1889, Dr. E. W. Row, of Orange, Va., reports an interesting case of grain of corn in the windpipe of a boy four years old. After eating parched corn one day he had cough and dyspnœa which were partly and temporarily relieved by an emetic of apomorphia. About midnight, however, the symptoms returned with increased severity, and a foreign body could be felt moving in the trachea. The next morning tracheotomy was performed, and a large grain of corn was taken out of the windpipe. The child then recovered promptly.

In reporting this case, Dr. Row recalls a similar case, which he attended about thirty years ago, in which operative interference was not permitted by the family, yet the little patient continued to live, although he became reduced to almost a skeleton. He was finally relieved by nature, abscesses having formed and ruptured into the bronchus, washing out the grain of corn. This patient, after daily expectation of death, for more than a month, recovered. In commenting on these cases, Dr. Row says that in all cases where foreign bodies are suspected in the air passages, notwithstanding the dyspnœa and threatened asphyxia may, for the time, be partially relieved by relaxing remedies, yet, it is the imperative duty of the surgeon to watch the case closely, and to apprise the patient's friends of the probable alternative, so that both he and they should be fully prepared if finally operative interference is demanded. With respect to diagnosis of bodies in the windpipe he believes, when it is not impacted, the foreign substance can be easily felt in the trachea as it passes along that tube in the up and down movement caused by respiration; and also that a foreign body may be detected by auscultation, by the rapidity of the movement and suddenness of the "thud" (so to speak) when compared with the movement of mucus in the tubes. The impression of the latter upon the ear is more diffused, does not start so suddenly, pass so quickly, or stop so abruptly, and without a distinct "thud" before reversing its motion. He also suggests that chloroform is not contra-indicated in partial obstruction by a foreign body in the air-passages, where a great factor in the production of symptoms threatening asphyxia is dependent upon spasmodic muscular contraction.

Abscess of the Antrum.

A new diagnostic sign of abscess of the antrum was brought forward by Dr. T. Heryng, of Warsaw, at the Congress of Otology and Laryngology, held at Paris during September. The patient is placed in a dark room and his mouth lit up with a small electric lamp, placed above the tongue. Two bright red spots will then appear below the lower eyelids.

If the cavities are filled up with pus, or occupied by a tumor, these red spots will not appear, but as soon as the pus escapes or the cavity is washed out, the spots again become visible.

Cough Syrup.

The following is said to be an excellent remedy for convulsive coughs:

Sodium benzoate	5 parts
Mint water	40 parts
Distilled water	40 parts
Syrup of orange peel	10 parts

Mix. Dose, a teaspoonful may be taken whenever necessary.—*National Druggist*, Nov., 1889.

The Vitality of Trichinæ.

In the year 1882, Professor Pasteur and Professor H. Bouley conducted a series of experiments regarding the vitality of trichinæ in ham. At that time it was discovered that the trichinæ lived even after having been exposed to a temperature of 32° (Fahr.).

Quite recently these experiments have been resumed and it was discovered that the trichinæ were more active in fresh pork than in cured ham. It was also proved that their vitality was in no wise decreased after an exposure of several hours to a temperature considerably below freezing point. High temperatures, up to about 80°, seemed to agree with them equally as well. Pasteur further states, in the *Bulletin Medicale*, Oct. 6, 1889, that trichinæ were found most frequently in American hams, which, he said,

are cured with a mixture of sea-salt and saltpetre. In regard to this statement, it may be said that the well-known infrequency of trichinosis in the United States, and the importance of the commercial interest in pork in France, would make it interesting to know a little more about the condition of Pasteur's experiments and investigations.

Treatment of Acne of the Face.

The most rational treatment of facial acne should be based upon the following two principles: first, to allay the congestion of the skin as far as possible; second, to remove all causes which could give rise to the hyperemia of the face. To obtain these results, both internal and external remedies may be used. The direct care of the skin demands the principal attention. Every morning and evening the face should be washed with a fine sponge. The temperature of the water should be as high as the patient can possibly bear it. After washing, the skin should not be dried. Such a washing renders the skin extremely hyperemic. As soon as the water begins to evaporate from the face, the superficial blood-vessels become contracted, and gradually regain their lost tone. In many cases, this simple treatment will be all that is needed, and a speedy recovery will follow. In severer cases, however, the following solution may be employed:

℞ Hydrarg. bichlor. corros.,
Ammon. muriat . . . . . āā gr. xv
Emuls. amygdal. amar. . . . . f℥vij
M. et fiat lotio.
Sig. Apply morning and evening.

The following formula will be found to be of equal if not of greater efficacy:

℞ Aquæ destil. . . . . f℥jx.
Sulphur. sublim. . . . . f℥j.
Aetheris sulfuric . . . . . f℥iij–f℥jv.
M. et fiat lotio. Sig. Apply morning and evening.

The practitioner may, however, come across cases of such a stubborn nature that even these lotions will fail to effect a permanent cure. In such cases, the only remaining course of treatment is scarification. This procedure never fails to quickly relieve the congestion of the skin, and also causes the acne pustules to rapidly disappear.

Regarding the best advisable diet to be pursued during the treatment of acne, little need be said, other than that highly spiced and heating foods should be avoided.—*Allg. Med. Central-Zeitung*, Oct. 9, 1889.

Bacillus of Tetanus.

At the recent German Surgical Congress in Berlin, Dr. Kitasato, of Tōkyō, Japan, demonstrated the tetanus-bacillus, and claimed that he had succeeded in obtaining this organism free from other bacteria, in experiments made in the Berlin Hygienic Institute. Tetanus serum was shown on agar-agar, and after twenty-four hours the bristle-shaped tetanus-bacilli were present, along with various other micro-organisms. If the culture was now exposed to a water-bath at 80° C. for half an hour, only the spores of the tetanus-bacilli retained their vitality; all the rest perished. Inoculations with the culture produced tetanus with the development of the typical bristle-shaped bacilli.—*London Medical Recorder*, Oct. 21, 1889.

Chapped Hands.

The following is a pleasant and efficacious application for chapped hands:

℞ Quince seed . . . . . ½ ounce
Water . . . . . q. s.
Glycerin . . . . . 1 fluid ounce
Alcohol . . . . . 4 fluid ounces

Macerate the quince seed with a pint of water for twenty-four hours, stirring frequently, strain with gentle pressure through muslin, and make up the volume to 1 pint with water; then add the glycerine and finally the alcohol containing the perfume, and stir briskly. — *Pharmaceutical Era*, Nov., 1889.

Ulcer of the Stomach.

Dr. Tacke, in the *Deutsche Med. Wochenschrift*, Oct. 17, 1889, reports six cases of ulcer of the stomach, accompanied by hematemesis, which were cured by enforced rest of the organ. In this method all nourishment is given by enema until the ulcer has time to heal.

Of course the method suggested is only occasionally beneficial, yet it is surely worth a trial, as, in the majority of similar cases, all the efforts of the physician are fruitless.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

RARE SEQUELÆ OF TYPHOID FEVER.

Neuritis, osteitis and periostitis, are comparatively rare sequelæ of typhoid fever. They are so rare that many of the books do not mention their occurrence; and this fact may have induced observers to set down occasional cases as mere coincidences, and thus the sequelæ appear to be rarer than they really are. Very recently, however, Dr. R. Humphrey has met with a case of multiple neuritis following typhoid fever, of which he communicates an interesting account to the *British Medical Journal*. The patient was a little girl, three years old, whose typhoid fever was marked by cerebral symptoms. In the course of the fourth week the child complained of pain in the limbs, which were contractured; and the reflexes of the abdominal muscles were exaggerated. Then paresis of the legs, with abolition of the reaction to electricity, occurred. At the end of eight days the condition of the right leg had improved, but paralysis had extended to the abdominal muscles on the left side. Subsequently the motor paralysis gradually disappeared, until after the eighth week, the affected muscles—except the anterior tibial and the abdominal—reacted anew to the Faradic current.

Too little study has as yet been given to this form of neuritis to enable one to speak with precision of its pathology. Dr. Ugo Bassi (*Osservatore*, No. 9, 1889), who has studied it in connection with a case observed by him in a mason, says that the alterations in the nerves are sometimes parenchymatous and sometimes interstitial; the lesions are, moreover, disseminated, healthy portions of the nerve alternating with those containing foci affected with neuritis.

Clinically the polyneuritis which follows typhoid fever manifests itself first by disturbances in sensation, and then by disturbances in motility. Its onset is sometimes abrupt and sometimes insidious; the soft parts over the seat of the neuritis are often œdematous, the skin being cyanotic and shining; and the local temperature is lowered. The average duration of the neuritis is from two to eight months, and, according to Bassi, the prognosis is in general unfavorable.

As regards the other rare sequelæ of typhoid fever—osteitis and periostitis—Sacchi has observed two cases, an account of which he gives in the *Rivista Veneta di Scienze Mediche*, I, 1889. Dr. Demuth has also seen one instance, a report of which is contained in the *Deutsche Medicinal-Zeitung*, No. 58, 1889. The patient of Dr. Demuth was a man, sixty-seven years old, who convalesced from typhoid fever after an illness of four weeks. Fifteen days later, however, he felt pain in the upper third of the humerus, a little below the surface. The skin over the seat of pain became red and swollen, and at the same time the fever recurred. Fluctuation gradually made its

appearance and a small quantity of muco-purulent fluid was evacuated by an incision. The bone exposed by the incision was red, and its periosteum was detached. A number of small sequestra were subsequently discharged. Appropriate treatment was followed by recovery in two months.

Ebermaier, in a communication to the *Deutsches Archiv für Klin Medicin*, Vol. XLIV, 1889, recalls the fact that Freund bases his inaugural dissertation, published at Breslau, in 1885, upon twenty cases of osteitis following typhoid fever. Freund attributed the bone affection to the typhoid bacilli, but did not attempt to prove this conclusion by experiment. L. Fränkel and Simmonds subsequently experimented, but obtained negative results. Ebermaier, however, appears to have been more fortunate. He says he has succeeded in obtaining pure cultures of the typhoid bacillus on gelatine from the pus taken from the foci of osteo-periostitis with which two typhoid fever patients were affected. In conjunction with these two cases of osteo-periostitis, he gives an account of six other cases of the kind, which were observed in the medical clinic at Kiel.

The cases just referred to lead one to suspect that neuritis and bone affections following typhoid fever would be found more frequently if they were carefully sought for. There is very good opportunity to do this, especially in large city hospitals, where cases of typhoid fever may be met with at almost all times during the year. Careful study of the sequelæ of the disease would not only be interesting in itself, but might also lead to some valuable discoveries as to the etiology of the disease, and give information which could be usefully employed in an improved treatment. We commend this subject to our readers, many of whom have exceptional opportunities for study and clinical observation. In 1889, Dr. W. W. Keen, of this city, chose this subject for the Toner lectures, which he then delivered, and prepared a monograph which contains material of the greatest interest and instructiveness, and one which ought not to be overlooked by any investigator who wishes to make his studies complete.

SURGICAL TREATMENT OF ANEURISM OF THE AORTA.

Attention is called in the *British Med. Journal*, Oct. 12, 1889, to a case of aneurism of the aorta treated by the insertion of wire according to the method originally introduced by Moore, of London, who in 1864 introduced twenty-six yards of fine wire into an aneurism of the ascending aorta and proposed this as a regular method. The case of Mr. Gould is not new, as it was reported by Dr. W. H. White and Mr. Pearce Gould, at a meeting of the Royal Medical and Chirurgical Society, April 12, 1887. The patient was a man 48 years old, who had noticed a swelling of the front of his right chest five months before he came under Dr. White's care. On his admission to the hospital, November 20, 1886, a prominent swelling was found in the position of the right mamma, extending from the second to the fifth rib, and from the edge of the sternum to the axilla. It was the seat of forcible expansile pulsation, and over it was heard a harsh systolic murmur. For two months an attempt was made to cure him by rest in bed, with restricted diet, and the administration of fifteen grains of iodide of potassium three times daily. About the middle of January the swelling increased rapidly in size and became very prominent. On January 11, Mr. Pearce Gould passed thirty-two feet of steel wire into the aneurism through a canula, introduced in the third intercostal space. Much blood was lost during the operation, but the hemorrhage was stopped with a compress. The tumor now became harder and the pulsation more heavy in character, and from one of the two punctures made at the operation considerable serum drained for several days. On the sixth day the pad of lint

was fastened on more firmly. The next day there was great swelling of the subcutaneous tissue over the aneurism. Two days later the skin became gangrenous, and the patient died. At the autopsy it was found that the first part of the arch of the aorta was greatly dilated, and a sacculated aneurism sprang from its upper part. The thoracic portion of the tumor had a distinct though thin sac, but that portion which protruded from the chest was destitute of a definable sac, and was limited by infiltrated muscle. The wire, mixed with loose fibrinous clot, proved a very dense mass nearly filling the sac, to which, however, it did not adhere. The fatal result appeared largely due to the absence of a distinct sac to the outer part of the aneurism, and to the effects of the formation of a hard, solid mass in the aneurism, combined with rather firm external pressure applied for the arrest of the serous oozing.

The usual method of treating aneurism of the aorta consists in absolute rest, restriction to the most limited diet, and the administration of iodide of potassium, digitalis or ergot, or some combination of these drugs. This method has given excellent results in a number of cases, and there are few in which surgical procedures are justifible or likely to succeed.

One of the most successful cases of introduction of filiform material into an aneurism of the aorta was that of the late Professor Loreta, who, in 1884, introduced over two yards of silvered copper wire into an aneurism of the abdominal aorta, after opening the abdomen to gain access to it. The wound healed by first intention and the patient's condition improved rapidly and materially, the tumor diminishing from the size of a child's head to that of a walnut in seventy days, although the patient died three months after the operation from rupture of the aorta below the sac. Liebrecht, of Liége, in 1885, suggested combining the introduction of filiform material with partial occlusion of the lumen of the aorta by means of a ligature. This might prove a useful procedure. The combination of galvanism with the introduction of wire—as practiced by Mr. Barwell, in 1886—might be expected, on theoretical grounds, to have some advantages; but they have not so far been demonstrated in practice.

On the whole, the management of these cases is still an open field for the enterprise and ingenuity of surgeons, and the patience and wisdom of medical men.

VOMITING OF PREGNANCY TREATED WITH MENTHOL.

The most unpleasant symptom accompanying pregnancy is undoubtedly the vomiting which often occurs, and this is especially serious because our present knowledge of its therapy is most unsatisfactory, and, in many instances, the physician is at loss to know how to proceed. It is not unfrequent that all therapeutic measures fail and relief is only obtainable by the induction of abortion.

Guided by the fact that the trouble must be regarded as a reflex neurosis, and that, theoretically, drugs which would depress the reflex excitability should also act beneficially in this complication, Dr. Sigmund Gottschalk, of Berlin, has used menthol in this disorder with marked success. He employed a solution containing fifteen grains of menthol in five and a half fluid drachms of alcohol and five fluid ounces of distilled water. Of this he gave a tablespoonful hourly. In a case so treated, and reported in the *Berliner Klin. Wochenschrift*, October 7, 1889, the vomiting ceased after the third dose, although previously other remedies had been used unsuccessfully. The patient was able to retain food and subsequently made a rapid recovery. The drug was continued for three days, the dose being gradually decreased.

The use of menthol is continually widening and there seems to be good reason on purely theoretical grounds for expecting that the results obtained by Dr. Sigmund were not

in the nature of a coincidence, but that they indicate a rational addition to the therapeusis of the vomiting of pregnancy.

DEPARTMENT OF HYGIENE AT THE UNIVERSITY OF PENNSYLVANIA.

A very important announcement was made November 11, in regard to the University of Pennsylvania, namely that Dr. John S. Billings has, with the approval of the Secretary of War and of the Surgeon General, accepted the position of Medical Director of the University Hospital, to which he was recently elected, and that the duties of this new position will be so arranged as not to interfere with his duties as Medical Officer of the army at the Surgeon General's office.

It is also announced that the University of Pennsylvania is soon to have a new laboratory of hygiene to cost about $200,000; and that $100,000 have been already collected for this purpose. The Department of Hygiene has been under the supervision of Dr. Samuel G. Dixon, since the death of Dr. N. A. Randolph, who was recently one of the Editors of the MEDICAL AND SURGICAL REPORTER.

It was rumored at first that Dr. Billings was to supersede Dr. Dixon; but the Provost of the University promptly denied this rumor and stated that Dr. Dixon was still Professor of Hygiene in the University and in charge of the Laboratory of Hygiene, which has been equipped through his exertions and liberality.

It does not yet appear just what Dr. Billings will do at the University, but the probability is that he will be at the head of the Department of Hygiene. For this he is abundantly fitted, as he is recognized as an authority upon the subjects of hygiene and hospital construction and administration. The elaboration of the plans for the construction of the Johns Hopkins Hospital, and his coming will be a valuable accession to the teaching force of the University of Pennsylvania.

CLINICAL LECTURES AND REPORTS OF CLINICS.

The readers of the REPORTER have no doubt noticed the development of the clinic departments in this journal, in the form of condensed reports of Clinical Lectures, and Reports of Clinics in a more colloquial style. This is a department which is believed to be of great value and interest, and no pains are spared to make it the best that is possible.

Special reporters are engaged to get material of this sort in the principal centres of the world, and more will be secured if the readers of this journal desire it. To secure to these reports a thoroughly trustworthy character, every one is submitted to the lecturer for correction or approval before it is published. They may all, therefore, be regarded as authorized by the lecturers. By this means it is hoped that the MEDICAL AND SURGICAL REPORTER will be a means of bringing back to many of its readers the familiar voices of their old teachers, or bringing to others the new and progressive doctrines of their old medical schools just as they would receive them if they were still "on the benches."

It is trusted that this plan will meet with the approval of our readers, and any suggestions in regard to it will be received with pleasure.

THE NATIVE EGYPTIAN AS A SUBJECT FOR SURGICAL OPERATION. — The native Egyptian is an extremely good subject for surgical operation. Clot Bey, the founder of modern medicine in Egypt, has it that "it requires as much surgery to kill one Egyptian as seven Europeans. In the native hospitals, the man whose thigh has been amputated at two o'clock is sitting up and lively at six." Shock is almost entirely unknown, and dread of an impending operation quite an exception. In explanation may be noted the resignation inculcated by their religion; the very small proportion of meat in, and the total absence of alcohol from, their diet; and in general their regular, abstemious, out-of-door life.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

HYGIENE AND PUBLIC HEALTH. By Louis C. Parkes, M. D., Assistant Professor of Hygiene and Public Health at University College, London, etc. 8vo, pp. xvi, 471. With illustrations. Philadelphia: P. Blakiston, Son & Co., 1889. Price, $2.50.

Parkes' "Hygiene" has long held a deservedly high name as a text-book. It is to be regretted that both the book and the subject do not receive more careful study at the hands of medical students and practitioners. Good descriptions are given in it of water, its sources, purification, and examination for sanitary purposes; of the collection, removal, and disposal of excretal and other refuse; of air and ventilation; warming and lighting; climate and meteorology; soils and building sites; food, beverages, and condiments; exercise and clothing; and of the contagia, and communicable diseases and their prevention. The concluding chapters are devoted to some important statistics, and to an account of the standard solutions for quantitative analysis.

The book is well written, with conciseness but clearness. It is one of the best books on this subject for students, and is an excellent one to have on hand for ready reference by practitioners and officers of health.

TRANSACTIONS OF THE NEW HAMPSHIRE MEDICAL SOCIETY, at the Ninety-eighth Anniversary, held at Concord, June 17 and 18, 1889.

Dr. William Child, of New Hampton, declares, in his paper on "The Use and Abuse of Narcotics and Alcoholics," that the narcotic and alcoholic habit cannot be transmitted as an inheritance. He believes that the time will soon be when a real inebriate will be put under restraint, and that prohibitory enactment alone will not cure or reform intemperance: "the power of a substantial, earnest, healthful, thoroughly Christianized mother is greater than that of all the organizations this side of heaven." Dr. G. P. Conn, of Concord, read a paper on the "Disposal of Garbage," in which he spoke of the great dangers arising from refuse, especially at summer resorts; but he had no definite plan to propose to remedy the evil. In the paper of Dr. W. B. Porter, of Walpole, on "Pneumonia; its Mortality and Therapeutics," the treatment of pneumonia by wet compresses, cold or hot, with suitable adjuvants, is commended. He also expressed himself as favorably impressed with the results obtained by Dr. Turner, in the treatment of pneumonia with inhalations of cold air. The discussions on the three papers mentioned was earnest and instructive.

The appearance of the volume speaks well for the New Hampshire Society, and indicates a healthy condition of the profession in that State.

ON THE RESPIRATORY FUNCTIONS OF THE NOSE AND THEIR RELATION TO CERTAIN PATHOLOGICAL CONDITIONS. By Greville Macdonald, M. D. (Lond.), Physician to the Throat Hospital, Golden Square, W. 8vo, pp. 72. Boston and New York: Houghton, Mifflin & Company, 1889. Price, $1.25.

Dr. Macdonald records in this brochure the results of his investigations to determine three things: the degree to which the temperature of the inspired air is raised by the nose; the degree of humidity acquired under the same circumstances; and, thirdly, the chemical changes that take place in the air by passing through the nose alone. By a clever device of tubing containing a thermometer, the air was inspired by suction with the lips, in such a way that it had first to pass in at one nostril and out at the other before reaching the mouth; thus the temperature of the air was registered after it had passed through both nasal fossæ and out of the second nostril. Four to six deep inspirations generally sufficed to raise the thermometer to the highest point, when the inspired air was of an ordinary temperature. The temperatures recorded in the experiments indicates the remarkable fact that, whatever the atmospheric temperature, the inspired current of air on passing through the nose alone is raised or lowered in temperature, approximately to that of the blood.

To determine the second question—the degree of humidity acquired by the air passing through the nose—a known volume of dry air was made to pass through the nose and then through tubes containing calcium chloride, previously weighed. The author found that air in passing through the nose alone is completely saturated with moisture.

With regard to gaseous exchanges, the author concludes from his experiments that they take place in the nose between the gases of the blood and those of the air, just as they do in the lungs, and that to a not inconsiderable extent. The quantity of carbonic acid exhaled by the nasal mucous membrane is said to be proportionate to the number of degrees of temperature to which the air is raised.

The author's experiments are clever and interesting; they seem to establish the fact that the nose warms and moistens the air, and that it takes part in gaseous exchanges. The book is well written, the apparatus used in the experiments clearly illustrated, and the publishers, on their part, have maintained their deserved reputation by presenting the book in most handsome style.

A TEXT-BOOK OF ANIMAL PHYSIOLOGY, with introductory chapters on general biology and a full treatment of reproduction. For students of human and comparative (veterinary) medicine and general biology. By Wesley Mills, M. A., M. D., L. R. C. P. (Eng.), Professor of Physiology in McGill University and the Veterinary College, Montreal. 8vo, pp. xxii, 700. With over five hundred illustrations. New York: D. Appleton & Company, 1889. Price, $5.00.

Dr. Mills has endeavored in the present work to apply to physiology the teachings of Embryology and of evolution. This, he thinks, has not been done hitherto. He strongly protests against the common tendency to speak of certain conclusions, for various organs and functions, as though they applied to these organs in whatever group of animals found, or, at all events, in the case of man, no matter what the species of the animal that had been experimented on. The subjects of development and reproduction are introduced early in the book, for the purpose of using certain embryological facts to throw light upon the different functions of the body, and especially their relations and interdependence. We are disposed to think that both the change from the usual custom and the reasons for it are good. Clinical and pathological facts are introduced from time to time in order to indicate to the student how physiology bears upon medicine. This is also a commendable feature of the book.

The author says, in his preface, that his aim has been to make the book, from first to last, educative. He has succeeded; it is full of sound physiological

knowledge, presented as clearly as the inherent difficulties af the subject permit. While the book is large, it does not impress one as ponderous or bulky. Several things contribute to this desirable end: the paragraphs are numerous, and so are centre-heads and side-heads; so that the contents of the chapters are rendered easier to study and easier to remember. Moreover, the illustrations are copious and admirably clear; and, more than all, each chapter concludes with a summary—a method of generalizing which is extremely helpful to students.

We commend the book most heartily to students of physiology, human or comparative, as perhaps the best exposition of physiological knowledge from a modern point of view which has yet appeared in English.

Literary Notes.

The Christmas number of *Scribner's Magazine* is an unusually handsome one, and this is saying a great deal; for *Scribner's Magazine* is already one of the very best in printing, in paper, in literary contents, and in illustrations. An interesting paper is that by Dr. William Perry Northrup, on "The Pardon of Ste. Anne d'Auray," which is abundantly and beautifully illustrated. Another extremely attractive one is that by Mr. Edgar Mayhew Bacon, called "Notes of a Subtropic Study," which is calculated to attract many a traveler to the delights of the Bahamas. Altogether the December number of this magazine furnishes abundant evidence how *Scribner's Magazine* has so quickly attained a circulation of over 125,000 copies.

Notes and Comments.

New Remedies in the Treatment of Phthisis.

We have had occasion from time to time to refer to various new methods and remedies in the treatment of phthisis, and have quoted at some length the results obtained by Houzè with tannic acid, by Ransome with inhalations of oxygen, and the excellent *résumé* of Shingleton Smith of the drugs suggested by the germ theory of this disease.

Paul Chéron (*L'Union Médicale*, Nr. 104 and 105, 1889), in a review of the therapeutics of phthisis adopts the classification of Gilbert, and divides the new remedies directed towards the relief of this disease into: (1) Inhalations; (2) powders; (3) gaseous applications (method of Bergeron); (4) injections; (5) internal antiseptic medications; (6) modifications in climate; (7) non-medical external methods; and (8) symptomatic medication. Carbonic acid, since the experiment of Weill, has not received much attention; Nothnagel and Rosback doubt its utility. Sulphydric acid has been employed by Allevard and studied by Niepce; the patients respired during an hour 52 litres containing one-half of the gas, and good results were obtained in the first and second stages of the disease. Sulphurous acid, as we know from the researches of Dujardin-Beaumetz, produces modification of the catarrhal state with diminution of the expectoration and lessening of the cough. Inhalations of iodoform and of terebinthinate essence have yielded contradictory results; benzoate of soda has been abandoned.

Hydrofluoric acid has been, as is well known, the subject of much experimentation, and the following are some of the results: Raimondi reported to the Congress on Tuberculosis, in Paris, 128 cases treated by the inhalation of the vapors of this acid with a cure (disappearance of the bacilli) in 28, amelioration in 18 who had cavities; 5 died of acute pulmonary processes. Gaeger (*Deutsch. med. Wochenschrf.* 29, 1888) obtained in 5 cases disappearance of the bacilli from the sputum and considerable diminution in the physical signs; in 7 cases there was notable local improvement; in 2, with laryngeal phthisis, the inhalations provoked inflammatory reaction. Andollent concludes from seven observations that the inhalations act rather upon the general tubercular condition than upon the local pulmonary lesion. He secured a rapid return of appetite and lessening of the dyspnœa by the use of this method. Tisné (*France med.* 82 and 83, 1889) tried inhalations of hydrofluoric acid vapor in 46 cases, 32 of which had not passed the second stage of phthisis, and produced amelioration in 13 instances; in 16 the disease remained stationary, while in 3 it was aggravated. In emphysema and asthma Tisné was able to confirm the reservation of Chevy that the inhalations must be employed with great caution, as they may provoke attacks of suffocation. Gilbert, who has treated 30 cases, with benefit to 19, negative results in 3, aggravation of the disorder in 3, and 5 deaths, recommends the following formula, which is sufficient to use for six days:—

℞ Hydrofluoric acid,
Water . . . . . āā ℥x

and concludes from his study that this method gives the best results among the newer inhalation-remedies. This conclusion is by no means in accord with the observations of all observers, thus Lépine, it will be remembered, was unable to dis-

cover any improvement in his cases, and Daremberg failed to secure beneficial results in the treatment of phthisis. Neither is this statement in accord with direct experimentation, since we know that Graucher and Chautard in their researches reached the conclusion that the vapor was of little value, and that, although if used for prolonged periods of time, it diminished the virulence of the tubercle bacilli, it did not kill them.

Among the internal remedies Chéron reviews the results obtained by Laskoff (*Nouveaux Remèdes*, 1889, 350) with the use of homeriana, a Russian plant which has an irritating oil for its active principle, and which the author prescribes in the form of a decoction or infusion:

℞ Infusum homerianæ . . . . . ℥j
Distilled water . . . . . Oij
To be taken in 24 hours.

With the exhibition of this remedy he obtained beneficial results in 90 out of 112 cases of phthisis, securing reduction of the temperature and diminution in the amount of the sputum.

Lashkewick has used the borate of ammonium in the dose of 3½ grains thrice daily, and found under its influence a notable lessening in the quantity of expectoration, and reduction in the febrile reaction.—*Univ. Med. Magazine*, November, 1889.

Death after Ether Anæsthesia.

A case of death from ether inhalation recently occurred at Bellevue Hospital. The patient was a male, and the ether was being given by Dr. Theodore, of the house staff of the hospital, preliminary to an operation upon the throat. The coroner's jury in the case rendered a verdict that death was caused by asphyxiation due to the administration of ether, complicated with cystic degeneration of the kidneys. Dr. Dunham, however, is of opinion that death was due to heart failure, rather than asphyxiation. All the usual precautions were taken in the use of the anæsthetic.—*Boston Med. and Surg. Journal*, Nov. 14, 1889.

Removal of Powder Stains.

Powder stains are frequently a source of annoyance from a cosmetic point of view. The methods hitherto in vogue for their removal have been more or less imperfect. The latest is, however, quite successful in its action and is very easily applied. The following solution is painted on the stains:

℞ Ammonii biniodidi
Aquæ destillatæ . . . . . āā f℥i.

This will turn the stains to a reddish color. To get rid of the red discoloration, it is only necessary to paint the affected parts with dilute hydrochloric acid. — *Medical Chips*, Sept., 1889.

New Tænicides.

Areca nuts are brought from India, Ceylon, and the Philippine Islands. The *Areca Catechu*, of which they are the fruit, is a palm. Arecaline is the active principle, and it is to this that the tænicide property of areca nuts is due. In its chemical composition and its properties, this alkaloid bears a marked resemblance to pelletierine, the active principle of pomegranate. Arecaline is an oily, volatile liquid, with an alkaline reaction; it is soluble in alcohol, ether, chloroform, and water. With acids it forms soluble salts.

Areca nuts are given in the form of powder; the dose is from a drachm to a drachm and a half. The alkaloid has not yet been administered with tænicide intent.

The rules for the administration of the areca powder are much the same as those given for the administration of pomegranate bark or pelletierine. Arecaline being a poison to the worm, benumbing and paralyzing it for the time, the administration of the nuts must be followed by an active purge to remove the entire worm before it has time to recover from its stupor. It is well to precede the ingestion of the remedy by a milk diet, and by a purgative or enema the evening before, that the intestines may be cleared of fecal matters, and that the drug may have a better chance of coming in contact with the worm. The helminth is generally expelled entire four or five hours after the ingestion of the remedy.

Another tænicide is the fruit of the well-known cocoanut, *cocos nucifera*. For a long time the albumin of the cocoanut has been prescribed as a tænifuge in countries where the *cocos nucifera* grows. Berenger-Teraud, however, says that he has made trial of this remedy a great many times, and only once out of twenty-four succeeded in ob-

taining the expulsion of the head of the worm.

Pariso, of Athens, writes that while he resided in Abyssinia, where it is the fashion to have tape-worms, he chanced to discover the tænicide properties of this albumin. On his return to Athens, he tested it thoroughly, and always with satisfactory results, the whole worm being expelled dead.—*Boston Med. and Surg. Journal*, Oct. 10, 1889.

Stuttering.

It is a well-known fact that stutterers, when speaking in a whispering voice, show no impediment of speech. A new method of treatment has been advocated by Dr. Coen and is as follows: In the first ten days speaking is prohibited. This will allow rest to the voice, and constitutes the preliminary state of treatment. During the next ten days speaking is permissible in the whispering voice, and in the course of the next fifteen days the ordinary conversational tone may be gradually employed.—*Kansas Med. Jour.*, Oct., 1889.

Roach Destroyers.

Roaches may be exterminated if the following powder is liberally sprinkled in the cracks and corners of their *rendezvous*.

Borax	37 parts
Starch	9 "
Cocoa	4 "

Mix.

Administration of Anæsthetics.

At a meeting of the Brooklyn Surgical Society, June 6, 1889, Dr. Pilcher said: The experience of the past ten years has led me to give preference to that very popular and common inhaler known as the Allis inhaler.

Practically, for the administration of ether, it has seemed to me that the simple cone of Allis, used with that intelligence and care which ought to accompany the administration of an anæsthetic always, gives us all we desire, with the one exception of not being economical of the anæsthetic. It is true, I have seen the anæsthetic poured through it on to a patient, which ought not to be, and need not be. Of course a recent graduate, though a fool, will not err in this way in the use of ether with this instrument presented by Prof. Wight; he couldn't pour the ether into the mouth of the patient if he should try. Certainly this is an advantage if to such hands the giving of an anæsthetic must be entrusted. I certainly like this instrument. It seems as simple as anything of the kind can possibly be and answer to the indications.

I am convinced that in a very considerable portion of cases the use of ether as an anæsthetic is dangerous, and have been rejoiced to see the tendency, which is so marked in the profession at present, to study the advantages and dangers of different anæsthetics with regard to different patients, and to suit to particular patients the anæsthetics which experience shows to be the best adapted for them; so that there is rapidly becoming less partisanship with regard to this or that anæsthetic. It is a marked feature, for which I think all thoughtful surgeons should rejoice, in the conditions of to-day. The long administration of ether is certainly depressing. Even the short administration of ether has a more or less irritating effect upon the respiratory passages. Ether to any considerable extent has also an irritating effect upon the urine-secreting apparatus, and it is certainly wise for us to take these things into account in choosing our anæsthetic; and if for any reason we feel we must use ether as an anæsthetic, it seems especially wise that we should take advantage of some such device as this which has been presented to us this evening, which would diminish as much as possible the irritating effect of that particular anæsthetic.

In many cases I am convinced that chloroform should be used as the anæsthetic rather than ether; in all cases where there is recognizable irritation of the bronchial and pulmonary tissues, also where there is a diseased condition of the urinary secretive apparatus; that in young children, likewise, who as a class have been shown by experience to be peculiarly pleasantly affected by chloroform, it should be used; and at the other extreme of life, in the aged, who as a class either already suffer from or are on the verge of renal and pulmonary degenerative changes.

Now, as to the methods of administering chloroform: The most convenient and safe inhaler is always at command in a common tumbler or a common teacup, into the bottom of which a handkerchief can be put so that it shall be an inch or two away from the nostrils or mouth, and which, when put over the mouth and nose, cannot be forced

so close down upon the cheek upon either side that there will not always remain still considerable apertures at those points for the abundant admission of air with the chloroform vapor. This is nothing new, but I have had occasion so many times to suggest it to men of large experience and of age in the profession, whom I have seen attempting to administer chloroform in both wasteful and dangerous methods, that possibly it may not be out of place to notice this method in this connection.—*Brooklyn Med. Journal*, November, 1889.

Sycosis.

For the treatment of sycosis, or barber's itch, Dr. Rosenthal recommends that the seat of the affection be closely shaved every day and that the following ointment be rubbed in twice a day:

℞ Acidi tannici, ... gr. xlv
Sulphuric precipit., ... ʒ jss.
Zinci oxidi,
Amyli, ... āā ʒ iv
Vaselini, ... ʒ j
M. Sig.—Use twice daily.

In a month, he says, nothing remains of the eruption but a very slow disappearing eryhema.

Cocaine in Vomiting.

Dr. M. W. Everson, in the *College and Clinical Record*, September, 1889, speaks of the value of cocaine in the vomiting of pregnancy and the obstinate vomiting of gastric ulcer and cancer. He has also found it of use in the vomiting of entero-colitis of children, a disease which is so frequent in our large cities during the heated term, and in which vomiting is often so prominent a symptom. In the latter affection it is best given in combination with bismuth. To a child two years of age he gives $\frac{1}{16}$ grain of the hydrochlorate at a dose, and repeats it every few hours *pro re natâ*.

In the vomiting of pregnancy ⅛ to ¼ grain three times daily will generally be sufficient. A formula which has proved useful in the latter affection is the following:—

℞ Cocain. hydrochlorat., ... gr. ⅛
Ext. nucis vomicæ, ... gr. ⅙
Pulv. asafœtidæ, ... gr. ij.—M.
Fiat. capsu'a j.
Sig.—Three times a day, a half hour before eating.

Cocaine will be found of value where other remedies fail. Dr. Everson has found it successful in those cases of vomiting of pregnancy in which the so-called specifics, oxalate of cerium, etc., have failed. In gastric cancer it will often arrest the vomiting for days at a time, thus giving the stomach rest.

The formula he has used in a number of cases of cancer is the following:—

℞ Cocain. hydrochlorat., . . gr. ⅛–¼
Thymol, ... gr. ¼–½—M.
Ft. pil. j.
Sig —Three times daily.

In every case in which it was used the vomiting and pain were noticeably lessened, and the patient was made vastly more comfortable.

But regardless of the above special diseases cocaine is of use in vomiting from any cause. The most desirable way to administer cocaine is in pill form, but it may be given in solution when a proper vehicle is added. The drug can be given in suitable doses without fear of depression.

Epilepsy Following Vaccination.

Dr. Althaus has reported a case, in the *London Med. Recorder*, Oct. 21, 1889, in which epilepsy was apparently set up by vaccination. A healthy lad of 19, who, neither in his family nor in his personal history, showed the slightest trace of any neurotic tendency, was revaccinated in the ordinary way. The vaccine caused somewhat severe symptoms, but these soon passed off. A month after the operation he was seized with an epileptic fit, and since then he has had attacks of great severity about once a month. There is no doubt as to the nature of the fits, and no other cause but the vaccination can be assigned for them.

Laxative Powder.

The following will be found an agreeable laxative:

℞ Powdered anethum, Powdered senna, Sublimed sulphur } each 3 drachms.
Powdered cream of tartar . 1 drachm
Powdered liquorice . . . 4 drachms.
Powdered sugar . . . . . 1½ ounces.
M.—Sig. Teaspoonful to dessertspoonful to be taken at night in a little water.

—*Pharmaceutical Era*, Nov., 1889.

NEWS.

—An effort is being made to start another Woman's Medical College in Cincinnati.

—Dr. Richard Volkmann, the famous surgeon of Halle, died November 28, 1889.

—The Idaho Insane Asylum was destroyed by fire on November 25, and eight lives were lost.

—Subscriptions amounting to $31,000 have been raised in Paterson, New Jersey, for the erection of suitable buildings for the General Hospital of that city.

—Dr. R. S. Huidekoper has resigned the Professorship of Internal Pathology and Zootechnics in the Veterinary Department of the University of Pennsylvania.

—By a gift of $5,000 to the Presbyterian Hospital in Philadelphia, Mrs. E. P. Baugh and son have endowed a free bed in that institution in memory of the late Mr. Baugh.

—A chair of Hygiene and Physical Culture has been endowed, in the sum of $25,000, at the Pennsylvania College at Gettysburg, by the parents of the late Dr. Charles H. Graff.

—A Training School for nurse girls is to be opened this month at the Babies' Hospital in New York city. This hospital is now permanently located on the corner of Fifty-fifth Street and Lexington Ave., and has a capacity of 35 beds.

—An epidemic of influenza is spreading in St. Petersburg, Russia. Half of the population of the city is said to be suffering from the disease. Among the victims are the Czar and Czarina and two of their children. There have been no fatal cases.

—Cholera is still on the increase in Persia, and the Russian authorities propose establishing at Bakou and Julfa a general quarantine against arrivals from Persia. The disease has now reached Kermansha, but has not yet made its appearance at Teheran.

—Dr. John S. Billings, with the approval of the Secretary of War and of the Surgeon General, has accepted the position of Medical Director of the University Hospital in Philadelphia. He will not relinquish his position as Medical Officer of the Army at the Surgeon General's Office.

—A new use for carrier pigeons has been found in Russia. The birds are used to carry negatives of photographs taken from balloons. The negatives are placed in envelopes impenetrable to light and can be conveyed in safety to great distances. These envelopes are tied to the birds' feet.

—The officers and friends of the University of Pennsylvania have organized a stock company under the name of the University Press for the purpose of controlling under one efficient direction the present periodical publications of the University, and of establishing such new magazines as the needs of the institution may suggest.

—By the late Dr. Ricord's will the Academie de Médicine was left 10,000 francs, the French Surgical Society, 5,000 francs, and the Society for the Advancement of Medicine in France, also 10,000 francs. His large library was bequeathed to the Midi Hospital. It is also stated that the Midi Hospital shall hereafter be called the Ricord Hospital.

—Acting upon suggestions in a communication signed by Drs. S. Weir Mitchell, D. Hayes Agnew, William Pepper, J. W. Da Costa, W. W. Keen, H. C. Wood, and William Hunt, the Board of Health of Philadelphia, on November 29, adopted a resolution in which it "strongly advises the boiling of all drinking water and milk at least 20 minutes, as the simplest and best means of purification."

—The forty-third anniversary of the New York Academy of Medicine was celebrated on the evening of November 21, 1889. Dr. William M. Polk delivered an address on "The Relation of Medicine to Some of the Questions of the Day." The President, Dr. Alfred L. Loomis, stated that the building fund of the Academy now amounted to $150,000 and it was hoped to realize $70,000 from the sale of the premises now occupied. Subscriptions of $20,000 additional were still needed for the completion of the new building.

—Dr. Lauder Brunton, who, as our readers are aware, proceeded to Hyderabad on Oct. 4, on behalf of *The Lancet*, for the purpose of repeating and amplifying the experiments made by the Hyderabad Chloroform Commission in 1888, with a view to confirm or correct its conclusions, telegraphs to that journal that the work is progressing in an entirely satisfactory manner. He has completed 275 experiments on dogs and monkeys, and the result so far has been to practically confirm the conclusions arrived at last year by the Hyderabad Commission. The telegram adds that the Nizam's Government is acting in a most liberal manner, and, in conclusion, states that the Nizam and the British Resident paid a visit to the laboratory on Monday last and inspected the work.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe, and healthful HOME.

HYPNOTISM IN HYSTERICAL PARAPLEGIA.—NIGHT TERRORS.—LEAD-POISONING.[1]

BY H. C. WOOD, M. D.,

PROFESSOR OF NERVOUS DISEASES IN THE UNIVERSITY OF PENNSYLVANIA.

Gentlemen: Our first patient, to-day, is a woman, 55 years old, admitted to the hospital one month ago. Her history runs as follows: Three weeks before admission she had experienced a tingling in the fingers, accompanied with a loss of taste. This was followed by numbness in the lower limbs and heaviness of the feet. In one week's time, she could not stand upon her feet. In this condition she was admitted. There was no loss of control over the bladder or bowels, and there was no loss of sensation in the limbs. The reflexes were abolished, and the knee-jerk was gone. Some spots of local anæsthesia were found, but no evidence of general anæsthesia. When we find a mixture of symptoms in a woman: a crossing and contradiction of the lines of several distinct well-known nervous diseases, then look out for hysteria. There are here no marked signs of hysteria beyond a general hysterical appearance, but undoubtedly this is a case of hysterical paraplegia. To-day there is slight return of the knee-jerk, which is reinforced by muscular movement and the woman is now able to walk. She has been treated and cured by hypnotism, which is, as you know, an artificial sleep produced by various means. This form of treatment is greatly in vogue among the French specialists; its effect is supposed to be due to "suggestions" given to the patient while in this state and these "suggestions" are supposed to act after the hypnotic state has passed. The condition wished for, is made

[1] Delivered at the Hospital of the University of Pennsylvania.

the subject of the suggestion. It is claimed that it exerts sufficient power to even alter organic structures. Wonderful examples are cited in support of this claim. I saw in the clinic of Luys in Paris, a male patient who was told to shake hands with a certain gentleman on awakening from his sleep. He awoke, sprang up and picking out the gentleman shook him by the hand, but was unable to explain why he had done so, simply feeling an irresistible desire to perform the act. Another patient was told while in the hypnotic state, that on a day just one year from that day, he was to go to a certain house where he would see animals and outlandish sights. On the date suggested he went to this house and imagined he saw these things he had been told to expect, but which, in the intervening time, he had not been asked to recall. While standing in the Paris clinic, the idea occurred to me that the real influence was due not to the so-called "suggestion" but to the mental impression produced on the mind of the patient. Coming to the hospital and seeing the strange sights of the hypnotized patients, and expecting to be placed under a strange influence, naturally they are in a condition to be deeply and profoundly impressed. So I determined on my return to try its use without attempting to employ the "suggestion." This woman was simply hypnotized; no suggestion was made to her and the results watched. Ordinarily she would be told, while in the hypnotic state, that she would regain power in her limbs and that her present condition would pass away. All such statements or suggestions I have carefully avoided.

The next case is also a woman, age 35, who is suffering from the unusual form of hysteria, called hysterical tremors. This is a condition simulating paralysis agitans which is, as you know, an incurable disease. Luys had a man in his clinic whom he claimed was cured of paralysis agitans by hypnotism; as soon as I saw him, I was convinced that the patient had had simply hysterical tremors. He had, while I was present, an hysterical attack, and I believe that he never had anything more. Curiously enough, immediately on my return I found this case which I believe to be similar to Luys' patient. This woman is decidedly hysterical in appearance and had that constant tremor which is so characteristic of paralysis agitans. She has been hypnotized regularly and has recovered fully, also without the use of "suggestions." I have been unable to obtain that the degree of hypnotism, called the somnambulic stage, undoubtedly on account of the less sensitively formed nervous systems of our American patients. As we approach the Latin races of Europe, we find them far more susceptible to hypnotic influences than the races living in the north of the continent; this is due to the more highly developed nervous systems of the southern people.

There are three types of hypnotism, the cataleptic, the lethargic, and the somnambulic; the cataleptic, we can produce in this woman, and undoubtedly we could give her "suggestions," but unfortunately she is so deaf that the effort of hearing awakens her from her cataleptic state. The somnambulic stage we have not been able to produce; it is far easier to produce in a member of the Latin race than in the class of patients which we meet here. Our patient was hypnotized by the use of revolving mirrors, on which she was told to keep her attention, showing that hypnotism is not due to the power of the operator, but can be produced by mechanical influences. There are a number of ways of inducing the hypnotic state, used by different physicians. They consist in some modification of sensory impulses from the periphery of the body. Stroking the eyelids gently, gazing steadily at some bright object, gentle friction or pressure on various parts of the body, all accomplish the purpose in different cases. In other cases where we tried hypnotism, we have not met the success which we have seen in these two cases.

Night Terrors.

Our next patient is a boy, eleven years old, whom his father brings to us for "night terrors." At first, the attacks occurred in the night; the boy waking his parents with his screams and yells. These began when he was but three years old and continued steadily up to May, 1889. He was always wakened with difficulty and at times had that condition of perverted consciousness, in which he recognized his parents, but believed himself beyond their help or sympathy. But six months ago the character of the attacks changed; he was seized in the day-time with a curious spell, in which he ran in a circle and fell upon his face. When picked up he was unconscious and restored to sensibility with difficulty. Two weeks

later he had another similar attack. Three weeks after this, on rising early in the morning, he lay down, had a tremor and a little froth was noticed at his mouth. This attack lasted three minutes. He does not know when the attack is coming on, and since they are instituted the night terrors have ceased.

Night terrors are not rarely the precursors of epilepsy; therefore it is necessary to blunt as far as possible the sensibility of the little patient. Stimulants must be avoided, coffee, tea, and similar articles; study should be laid aside, farm-life is excellent, for hygenic purposes; and the case encouraged to all sorts of out-door athletic sport. This boy is a farmer's son, and has led a busy, outdoor life, but in his case I believe the trouble to be epileptic. If put on the bromide treatment, we can accomplish a great deal, although an actual cure is doubtful. With conscientious treatment, we may be able to make the attacks come years apart.

Argyria.

The next patient is a Pole, unable to speak or understand English; so his history is more or less in doubt. He is extremely anæmic, as you would expected in lead-poisoning; he has the blue line along the gums, and he is, we have learned, a worker in lead. But on turning down his upper lip we find it discolored with lead. In argyria, this point is the first to look for discoloration, the silver staining appearing here before it shows in the skin, but this is the first time I have seen such a thing in lead-poisoning.

Sawdust as a Dressing for Wounds.—*Cosmos* suggests the use of fine soft sawdust as a dressing for wounds, and as a vehicle for medicaments or antiseptics. It says that the dust, freed from splinters and sharp bits of wood by sifting, when used alone and dry, makes a clean and grateful dressing; that it readily takes up and holds the discharges without packing or adhering; and that it is easily rendered antiseptic by any of the methods used in preparing antiseptic cotton or wool. The *St. Louis Medical and Surgical Journal* suggests that our yellow pine sawdust, rich as it is in turpentine, would prove of itself a valuable antiseptic application.

FRACTURE OF THE INFERIOR EXTREMITY OF THE RADIUS AND ULNA; FRACTURE OF THE ELBOW JOINT; PERFORATIVE APPENDICITIS, ABDOMINAL SECTION, EXCISION OF THE APPENDIX.[1]

BY THOMAS G. MORTON, M. D.,

ONE OF THE ATTENDING SURGEONS TO THE PENNSYLVANIA HOSPITAL, PHILADELPHIA.

Fracture of Radius and Ulna.

Gentlemen: I am able to show you this morning specimens illustrating fracture of the inferior extremity of the radius and ulna. It is very unusual to obtain recent specimens of such fractures, for injuries of this kind almost always end in recovery. The patient from whom this specimen was obtained was admitted to the hospital with compound depressed fractures of the skull, complicated with grave injuries elsewhere. In a few hours the patient died.

These photographs I show you of the hand and forearm show very well the deformity which was originally described by Velpeau, and which is now generally known as the "Silver Fork" deformity. An examination of the dissected bones shows an irregular, transverse fracture of the radius half an inch above the wrist joint. On the outer side of the inferior radial fragment we find a vertical fracture, which extends into the carpal articulation. The extreme end of the styloid process of the ulna is also fractured. The upper fragment of the radius was driven under the lower fragment and firmly held by the soft parts in this position.

There was no impaction, and no dislocation of the ulna. As I hold the fractured bones in this position, the result of the accident, you can readily observe the deformity to which I have already called your attention.

The treatment of all fractures in this region consist, first, in promptly reducing the deformity; and it is always advisable to place the patient under ether. The splint may suit your convenience—a single straight, or two straight splints, one on each side of the arm, is all-sufficient. Some surgeons prefer the pistol-shaped splint; others, the Bond splint, which is somewhat curved outward;

[1] Delivered at the Pennsylvania Hospital, Nov. 9, 1889.

at that part on which the hand rests, either a block of wood, or a roller bandage is fixed so that it shall be grasped by the hand. Such a dressing permits free movement of the fingers. No matter what apparatus, however, is used, be certain that you reduce the fracture.

Fracture of the Elbow Joint.

This patient was admitted a week ago with an injury about the elbow. There was pain, swelling, deformity, and crepitus, on account of the swelling. The arm was simply placed on a pillow, and elevated; then covered with towels saturated with lead water and laudanum. On the subsidence of the swelling the arm was placed upon a right angle splint, and carefully bandaged from the hand to the shoulder, to hold together the separated condyles of the humerus, and also to keep the arm at rest.

In treating fractures avoid early tight bandaging, for considerable swelling is likely to take place as a result of the injury.

In a fracture of the middle of the forearm, see that you have the arm in a correct position, and the radius and ulna normally separated; the thumb should be upward and outward, and the palm of the hand present somewhat upward and toward the patient. Two splints are all that is required; one should be on the inside, extending from the bend of the elbow to the ends of the fingers, and the other on the outer side from the elbow to the wrist, or slightly beyond the carpus.

In fractures of the olecranon a straight splint should be applied from the middle, or upper third of the arm, to the wrist or hand; after three weeks, gentle flexion of the elbow may be commenced, and, generally, the union is good. If there is some separation of fragments, as sometimes occurs, with fibrous union, no serious results need be anticipated. I have never seen the necessity for wiring a fracture of the olecranon, but there would be no danger in so doing under the present methods of wound treatment.

For fractures of the humerus, at any point, a right angle internal splint is all that is required, but the simplest and best form of splint is that which the patient supplies in his chest wall which answers admirably. A towel or some old linen, or other soft substance, should be placed on the patient's chest, the arm is then confined to the side by a roller bandage, which should be carried over the shoulder; a pad of cotton may be required to overcome any deformity. Such a dressing should be changed every second or third day, until union has taken place. An external pasteboard splint, moulded to cover the shoulder and arm, answers a good purpose in steadying the fractured bones. The weight of the arm, however, is generally sufficient to overcome any disposition to deformity.

It is well in fractures of the elbow joint to use flexion and extension very early, by this means we overcome in a measure the disposition to partial or complete anchylosis; if the latter is likely to occur, let the angle of anchylosis be an acute rather than a right angle, the former being so much better for future use to the patient.

Perforative Appendicitis; Abdominal Section; Excision of the Appendix Vermiformis.

On Nov. 5 I saw, in consultation with Dr. C. H. Shivers, of Haddonfield, N. J., a lad of eleven years who had a few days before been accidentally struck by the handle of a spade in the right iliac region; intense pain followed, but the boy was not wholly confined to his bed until the day subsequent to the injury; on the fifth day there was a temperature of $101\frac{4}{5}°$, pulse 110, respiration 44, dry tongue, right iliac region very tense, exceedingly painful to slightest touch; no pain on left side of belly, there was no localized fulness or tumor, and no dulness on percussion; the bowels had been kept freely moved by salines. The boy had two days before a very slight rigor, and followed by decided perspiration; careful inquiry brought out the fact that on very many occasions during the previous two or three years, the boy had attacks of colic, thought to be due to an internal hernia, the symptoms disappeared, but the pain, however, was always in the appendix region; with this history I felt convinced that there had been chronic appendicitis, with probably a foreign body in the organ, and the injury produced by the blow of the spade handle had lighted up an attack of acute inflammation in the already diseased appendix, which becoming ulcerative had ended in perforation, and that although all of the symptoms of abscess were not present, yet undoubtedly pus had formed, and as the boy had progressively grown worse, the danger was from extension of inflammation, or the abscess bursting into the peritoneal cavity. Lat-

eral abdominal section was performed on Nov. 6; the incision began an inch above the middle of Poupart's ligament, and to the outer side of the right linea semilunaris and was continued upward and outward for four inches; reaching the colon, and turning this in search for the appendix, an abscess was found containing from an ounce and a half to two ounces of very fetid pus; the appendix was found partially glued to the cæcum; it is enlarged, as you see, thickened and covered with lymph, and showing a perforation, which was responsible for the whole trouble. This intestinal concretion was found in the perforation; a silk ligature was placed on the appendix close to its root and the remainder was excised. The peritoneal cavity was flooded with large quantities of recently boiled water; a large glass drain tube was inserted into the wound and carried to the bottom of the pelvis and a rubber tube was placed in the abscess cavity alongside of the colon; the wound was then brought together with silk sutures; a flannel bandage and a mass of absorbent cotton held the tubes in position; milk was ordered at short intervals. The glass drain tube is kept in working order by a rope or wick made by twisting absorbent cotton. This can be changed as often as it becomes saturated with secretions from the belly cavity, and before a fresh wick is replaced the tube should be pumped out by a long-nozzled syringe. The bowels in such cases should be kept in a soluble condition after the operation by calomel and salines, there is no occasion for the use of opium, while threatened peritonitis should be treated by active purgation by salines.

The very great importance of this subject may be better understood by you, when, it is stated by Mr. Treeves that in England, alone, more than two thousand persons die of peritonitis, and it is probable that a very large proportion of these cases result from appendix disease, and I have already said that this worse than useless organ must be regarded as the root of most evil in the region under consideration.

From numerous dissections I have found that the normally placed appendix can always be found immediately under a point two inches distant from the right anterior superior spinous process, and on a line drawn horizontal from this process toward the median line of the body. There are of course many cases of simple typhlitis, which recover without operation, but a tedious recovery, recurrence, or relapse, point to a probable presence of surroundings exceedingly dangerous to the patient, and to the appendix as the source of the trouble. When the diagnosis of pus, even a small amount, has been made, the course for the surgeon to pursue is plain; indeed, now and then without positive diagnosis of pus, it would be safer to operate than to take the risk of having suppuration so near the peritoneum.

The foreign body usually found in the appendix, as in the specimen I show you, is composed of inspissated fecal matter; occasionally other substances find their way into the organ, but such is the exception. In about 80 per cent. of autopsies, the appendix will be found more or less occupied by fecal concretions. These are apt to be soft and easily indented by the finger nail, though at times salts are deposited in this material and calculi or enteroliths are thus formed.

In amputating the appendix a silk string should be tied upon the base of the appendix as near to the cæcum as possible.

The position of the perforation in these cases varies, but probably the opening takes place near the situation of the foreign body; occasionally the extreme end of the organ sloughs. In the specimen before you the perforation was found half an inch from the end of the appendix.

I have so far made the diagnosis of perforation of the appendix with abscess and performed abdominal sections, in seven cases, with two deaths. Of the latter, one was a child, four years of age, in a state of collapse when the operation began, the second case I saw in consultation with Dr. E. E. Montgomery, of this city; the patient was a woman 50 years old, who had refused operation and only consented when in condition of collapse. She died in four hours. Four of the six cases have recovered; the last case, the one which I have just related to you, is in a fair way to recovery, for all the symptoms are most favorable.

In regard to the removal of the drainage-tubes, I may remark that so long as the secretion from pelvic cavity is considerable or there is the least odor the tube must remain; when there is little or no secretion it can be removed, when a rubber drain should be substituted, which, day by day, should be drawn outward and an inch or more removed. The discharge from the abscess region after a day or two readily reaches the surface without the rubber tube, so that very

early the latter can be dispensed with. Complete healing of the wound generally occurs in from four to six weeks.

COMMUNICATIONS.

IS INEBRIETY A DISEASE?

BY WM. F. MITCHELL, M. D.,
ADDISON, PENNA.

Without attempting any scientific discussion of this subject, the writer may be excused for offering a few thoughts in the columns of the REPORTER.

Theorists claim that drunkenness is as much a disease as inflammation of the brain, and that the disease is or may be one of heredity. In the REPORTER, Sept. 28, 1889, Dr. T. D. Crothers, of Hartford, cites a case at some length, in regard to a man who deliberately killed his wife. This man, after committing the crime, sauntered around the house for an hour or so, then walked over to a saloon, and drank several glasses of spirits, after which he gave himself up to the authorities.

The man's conduct in jail, for the next six months, was without note, excepting that he was depressed and melancholy, which one would naturally think a proper state of mind for such a villain to be in. The man made a plea of alcoholic insanity, or, in other words, emotional insanity; the refuge of so many cowardly murderers nowadays.

Dr. Crothers thinks his plea a just one, for some seven reasons. The criminal inherited alcoholic diathesis; he began to drink in his childhood; he did not live happily with his wife; had recently threatened to kill her; he had been violent at times, when drunk—which is a very common thing, in my experience, with drunkards,—and, of course, sorry for such actions when sober; he showed great excitement one week before the murder,—drank more than usual, is the inference—and because his wife went to church without his consent, he deliberately shot her while she slept. He was delirious and melancholy afterwards, up to the time of his trial—which condition would hardly occasion much surprise—and from all these alleged facts, Dr. Crothers testified his mind was unsound, and that he was irresponsible. The prosecuting attorney very properly, I think, argued that "intoxication was no excuse for crime," and "that no man can claim exemption from the law or the duty he owes his fellow-man, by saying he was without reason and control of himself," in consequence of having voluntarily made himself an outlaw by his actions. Dr. Crothers comments at length on what the medical experts said, and the charge of the Judge. The prisoner was righteously convicted, but died before execution. This is a fair sample of many cases cited in recent years by Dr. Crothers, only this is, perhaps, the only one who committed a murder when he had this alleged disease.

Dr. Crothers then comments further on this and other cases, holding the idea all the way through, that, because a man, endowed by the Creator with more than ordinary intellect, capable of making money, and accumulating property, deliberately gets drunk, and keeps on getting drunk, until he commits a monstrous crime, is to be held as irresponsible, ignoring the patent fact that this man, as an intelligent being, knew the consequences that would follow his indulgence in the vice, and the Doctor finds considerable fault with others, who differ with him in their views on this subject. Suppose Dr. Crothers' man had been acquitted, as he thinks he ought to have been, I presume his "melancholy and depression" would have left him, and, since Dr. C. does not say what disposition should have been made of him, doubtless he would have had him turned loose, to get another violent spell, and be ready to sacrifice another innocent life. Only a few weeks ago such a murder case was tried in the court of this, Somerset, county, the murderer being convicted of murder in the second degree, and an identical case with Dr. C.'s is on trial now in Pittsburgh, the plea being alcoholic insanity. A celebrated lawyer is employed by the defense. How do all such theories as these protect society? Who knows when he or she is safe? No man can tell when he leaves home how soon he may meet a man who has this dread disease of alcoholic insanity, or how soon his wife may be a widow, or his children orphans. A great many physicians think drunkenness is produced, many times, by the use of alcohol prescribed during some illness by the attending physician. In an experience of more than twenty-four years, I do not know of a single instance of any person becoming a drunkard because alcohol

had been prescribed, and I have made careful inquiry among the neighboring practitioners, and they all have a like experience. I always prescribe alcohol in some form, when it is indicated, as do all practitioners with whom I am acquainted. On the other hand, however, I know many individuals who became drunkards from choice, and by associating with evil companions.

I do not believe in the heredity of this vice. In the neighborhood where I practice, I know a number of men who were notorious drunkards themselves, and who raised large families of boys, not one of whom follows in his father's footsteps, so far as drunkenness is concerned, while I know whole families of boys who became drunkards—in whose ancestry there was no trace of the vice as far back as the generations were known—simply because those with whom they were associated were of evil habits, and their influence bad.

How a vice can be considered a disease, is beyond my comprehension, for any sane man knows that if he drinks alcoholic liquors to excess he must necessarily become a drunkard, and all he need do, to cure himself of this alleged disease, is to abstain from the use of them. The most ultra believers of this question will certainly not dispute this simple fact. Dr. Crothers' man would never have become a criminal if he had let liquor alone.

I believe, and I think the assertion is capable of demonstration, that nineteen out of twenty young men learn to drink intoxicating liquors, because, by doing so, they imagine they will look more manly in the sight of their associates, or because others want them to drink; and they have not the stability of character to refuse. For these or some other equally frivolous reasons, I presume the drinking habit is easier to acquire than the habit of using tobacco. Every boy has a desire to learn to use tobacco, and he will never be half so sick when he dies, as after his first chew or cigar will make him, yet he continues until he becomes proficient. He will spit and puff where some one can see him, vainly imagining he is a man. Drunkenness is learned for much the same reasons. I have very little patience with a physician who with light and knowledge before him, becomes a drunkard.

I have known a great many men who had drank liquor for years, whose appetites were so depraved that they would drink anything that would intoxicate, "stop short" like "Grandfather's Clock," become sober men and remain so all their lives, without any treatment whatever, and without knowing there was any such place as an Inebriate Asylum, or that some learned doctors regarded their vice as a disease. If every man who drinks to excess does as these men did, and as many men can do, I will guarantee no person will ever be afflicted with this disease.

These persons show no symptoms of disease, except what would naturally result from their vicious habits. A man may butt his head against a stone wall, and produce inflammation or congestion of the brain, or pour acids on his person until he would have something akin to phlegmonous erysipelas, but when he knows the results of such violations of nature's laws,—violations done with full knowledge of what would follow—could his deliberate actions be called a disease? He need not butt his head against a wall or burn himself with acid. Of course no one will deny that the continued use of intoxicating liquor to excess will produce changes in the system, and ultimately certain conditions, worse, perhaps, than anything that can afflict a man, yet the fact remains that the cause or these conditions—the vice of drunkenness—is not, nor cannot, be a disease. If a man is born with some deformity, or if he inherits tuberculosis, or some such disease, he is to be pitied, but when he diseases himself, by getting drunk, he deserves no sympathy. No man ever lived who could not stop drinking if he wanted to, even admitting, which I do not, the heredity of the vice. A man who has not the will power, or, rather, who will not exercise it, for he has it, to stop a vicious and dangerous habit, without going to an Inebriate Asylum for treatment, is of very little account in this world. The same may be said of any other useless and injurious habit—tobacco, morphia, etc.—and how unmanly it sounds to hear a sane man say "I would gladly quit the use of whiskey, morphia, or tobacco, if I could, but I can't." As if a man, formed after the image of the great Creator himself, should acknowledge his inability to govern a depraved and morbid appetite.

In a recent notice, in the REPORTER, of a book by Dr. Kerr, who cites the case of a clergyman, exactly after the fashion of Dr. Crothers, for whose downfall there was no earthly excuse, the REPORTER well says: "Dr. Kerr records with such a sympathetic

touch, which explains and excuses, but does not justify the act—the case is simply one in which a man yielded to temptation, and became a drunkard," and the "act which made him so was not caused by disease."

Here we have the whole thing in a nutshell, so plain, it seems to me, that a "wayfaring man, though a fool, need not err therein." Let the man say to the tempter: "Get thee behind me, Satan," and he will be a sound man, so far as this disease is concerned, all his life. Suppose the opinions of Dr. Crothers, and others who believe with him, should prevail in this country, how long would it be before criminals, of all classes, would take advantage of the alcoholic insanity dodge? If a man can get released, after committing a murder, because of alcoholic insanity, a less degree of this same insanity ought to prevent his conviction for arson, a still less degree for burglary, and so on down to the petty thefts and misdemeanors. It is said to be "a poor rule that won't work both ways," and one class of criminals should have the same privilege that another has.

It is gratifying, however, to know, that courts and juries have not, yet, taken this view of the matter, and we hope, at least, that when a man,—as occurred some time since in New York—becomes alcoholically insane, and gouges his wife's eyes out, or murders her in cold blood, as Dr. Crothers' man did, to see the vengeance of the law, and outraged public opinion visited upon him without delay.

EXCESSIVE HEMORRHAGE AFTER EXTRACTION OF TEETH—A CASE.

BY C. H. M. NEALL, M. D., D. D. S.,
PHILADELPHIA.

WITH REMARKS
BY T. D. DUNN, M. D.,
WESTCHESTER, PA.

Some time ago an elderly woman called at my dental office to have some teeth extracted. She enjoyed excellent health, and is the mother of two children. I gave her an anæsthetic—nitrous oxide gas—and extracted on the right side of the upper jaw the second bicuspid and the first molar, and on the left side the first and second bicuspids, and the first, second, and third molars.

Before leaving my office, the hemorrhage ceased. About two hours later the patient returned with copious hemorrhage from the right side of the upper jaw, but no hemorrhage from the opposite side. I cleaned out the cavities separately, and applied Monsell's solution on cotton.

The blood pressure was so strong as to wash the compress out completely of the cavities. Finally, by strong compression by means of a roller bandage, I checked it to a certain extent. The hemorrhage then came out of the ear. The patient was very much exsanguinated from the loss of blood. I gave internally gallic acid with ergot. After I had checked the hemorrhage, I applied the actual cautery to the alveolar cavities. It was fully one hour from the time the patient came in until she departed for her home. I was told by her physician that after she arrived home—which was about twenty miles from the city—the hemorrhage returned, and that he had the same trouble as I had had. I cannot understand why the hemorrhage was only from the right side. I pulled out more teeth on the left, and larger ones. I have heard that this woman would bleed for hours if she cut any portion of her body or even scratched her hand. This is said to occur only when she is cut upon the right side of the body. If she happens to cut herself on the left side, she will bleed only a short time.

Remarks by Dr. T. D. Dunn.

Unfortunately, in Dr. Neall's interesting notes there is no mention of a family disposition or tendency to bleed, without which there must be some uncertainty whether or not the patient is a true subject of the congenital and hereditary disease, hemophilia, which is the most hereditary of all diseases. The most remarkable family of bleeders on record lived in the village of Tenna, in the canton of Graubündten, as described by Anton Hoessli, who has traced the disease in his family to the year 1640, or for nearly 300 years. I think the fact of the bleeding being confined to the right side of the body in Dr. Neall's case is a mere coincidence. I can find no record of unilateral hemorrhage in this disease, and it would not be in accordance with our knowledge of its pathology. Probably, as has been pointed out, "two circumstances combine in hemophilia—a congenital frangibility of the vessels, and a defect in the coagulability of the blood; but whereon these depend we are as yet entirely ignorant."

The tendency to bleed after extraction of

the teeth, as after all minor operations, is exceedingly common in hemophilia. Hemophilists seem predisposed to rheumatic toothache, and frequently apply to dentists who are unaware of the bleeding tendency, instead of their medical adviser. They should, therefore, be especially warned of this danger by the family physician.

The treatment of Dr. Neall's case was very judicious. In several recorded cases, after the introduction of cotton into the alveolus, a cork has been trimmed to fit the cavity and by closing the jaw, held sufficiently firm, to control bleeding, the pressure being gradually withdrawn as the hemorrhage ceases. Ranger, in St. Thomas's Hospital Reports, vol. vi, p. 121, advises that an impression of the jaw should be taken with plaster of Paris mixed with salt and warm water, the jaw to be held in position by a compress and bandage. Before taking the impression the mouth should be thoroughly cleansed of blood.

The quantity of blood lost after extraction of teeth has in some cases been enormous. Krimer reports a case in which four and a half pounds of blood were lost in twenty-four hours, and Schaefer's case lost four pounds daily for several days after an extraction. Dr. R. Coates relates a case in the *North American Medical and Surgical Journal*, vol. vi, page 45, 1828, in which three gallons (24 lbs.) were lost in eleven days. Several bleeder descendants of Dr. Coates' patient have come under my observation and are reported in the *American Journal of the Medical Sciences*, January, 1883. The marked tolerance of bleeders for great losses of blood and the rapidity with which they recover after them are even more remarkable than the severity of the hemorrhages.

Proposed Medical Congress in Spain. —A meeting was recently held in the rooms of the Spanish Medico-Chirurgical Society at Madrid with the view of arranging an international medical congress to be held at Madrid in 1890. Though the proposal received influential support, the general feeling was that it would not be desirable to organize a gathering which should in any way clash with the congress at Berlin. The suggestion was thrown out that an attempt should be made to have the eleventh International Medical Congress held at Madrid in 1893.

UMBILICAL HEMORRHAGE: ITS TREATMENT.[1]

BY LLEWELLYN ELIOT, M. D.,

WASHINGTON, D. C.

Without entering into the etiology, the pathology, or the morbid anatomy of umbilical hemorrhage in the newly-born, I shall preface the introduction of my cases by a few general remarks upon the subject.

Text-books on Obstetrics, Diseases of Children, and General Medicine are mostly unsatisfactory in their treatment of this accident, and it is to journal articles we must have recourse for what is known concerning it. This neglect upon the part of teachers is due solely to the generally accepted belief that it is a rare occurrence. In this opinion I must differ, for cases of umbilical hemorrhage are not generally reported by physicians, owing to the fear of being charged with carelessness; again, midwives and nurses never report them. Where death follows this loss of blood, the death is stated to be from some other cause, as icterus neonati or congenital debility, since few of us care to record a death from hemorrhage.

Umbilical hemorrhage, in the newly-born, arises from carelessness in applying the ligature to the cord, forcible avulsion, fungoid excrescences following the separation at the point of ligation, or it may be of spontaneous origin. The blood is thin and watery, does not coagulate readily and may have its origin either in the arterial, the venous, or the capillary system. More cases occur in males than in females.

Accepting the figures of Dr. Joseph S. Gibb[2] as given by Hennig[3] and by Keiller[4] there were reported from 1752 until 1881, two hundred and thirty-six cases of umbilical hemorrhage. He adds one case occurring in his own practice; one reported by Dr. T. F. Prewitt,[5] one by Dr. W. H. Rouse,[6] and two by Dr. Boardman Reed;[7]

making in all two hundred and forty-one cases. To these I have to add one case reported by M. Louis Hirigoyen,[1] one by Dr. D. E. Sibert,[2] one by Dr. W. T. Plant,[3] four by Dr. J. Ingram,[4] one by Dr. W. H. Thayer,[5] one by Dr. Keser,[6] two by Dr. T. J. McCarty,[7] one by James Gilroy,[8] three by W. R. Dakin,[9] one by Dr. J. M. Van Cott, Jr.,[10] and my own four cases, making the total number of reported cases two hundred and sixty-one.

The treatment of umbilical hemorrhage is both local and constitutional. The local means employed consist in a new ligature, compression, the application of tannic acid, subsulphate of iron, acetate of lead, spirits of turpentine, plaster of Paris, collodion, and the ligature en masse. Those of a constitutional character consist in good milk diet, calomel, sulphate of soda, the tincture of the chloride of iron, aromatic sulphuric acid, the fluid extract of ergot, brandy, and a general tonic course. These means are many times unsuccessful, the child is jaundiced, weak, and exsanguined, and death must be the inevitable result. In such cases, there is one treatment which should receive the attention it merits, this is the performance of a laparotomy and the passage of a ligature about the cord, before its exit from the abdomen. This operation is difficult, is dangerous, and may prove unsuccessful, but it is the veritable last straw thrown to the drowning man, and even though death would not be prevented in some cases, the number that would recover would more than balance the risks assumed in doing the operation. My convictions upon this point are strong, and I write as an enthusiast. Although the only case in which I employed this treatment proved fatal, the fact of the arrest of the bleeding after the ligature was applied, leads me to believe, that had the operation been made before the child was exhausted, by bleeding, and therefore much valuable time lost, the result would have been different. As abdominal surgery is fast taking a place as an assured success, I can see no reason for this accident being denied the benefits of an early active treatment. Intelligent parents will permit any operation that promises even a shadow of success.

Case I.—In the winter of 1880, I was called to see Daniel B——, colored, aged three days. Physical condition good. Both parents healthy. Bleeding occurred on the morning of the third day, but was not very profuse. It was controlled by a new ligature, compression, and the application of Monsel's salt. Condensed milk was given by the rectum, and small doses of calomel to overcome the constipation and the beginning jaundice. This child recovered.

Case II.—E. W——, female, colored, born April 7, 1881, after an easy labor. Hemorrhage followed forcible traction on the cord by the mother. Pressure, styptics, and astringents failed to check the bleeding. Ligature en masse succeeded, but the child died exsanguined the same day.

Case III.—John A——, colored, born October 5, 1881, after a slow and tedious labor. Hemorrhage followed accidental traction on the cord on the third day. Styptics, astringents, compression, and the ligature en masse failed to check the hemorrhage. The child died on October 9.

Case IV.—Louisa A——, colored, born at one o'clock on the morning of March 19, after an easy labor of ten hours. The child was in a fair general condition. Meconium passed in due time. Hemorrhage from the umbilical cord occurred at eight o'clock on the night of March 19, as a slight oozing, which rapidly increased. A new ligature and a compress were applied with partial success. At half-past ten o'clock on the morning of March 20, I saw the case. The child was jaundiced, the evacuations from the bowels were white and clayey. The bleeding continuing, pins were passed through the umbilicus and thread twisted around them (the ligature en masse). This was successful for a short time, when bleeding again occurred. At eleven o'clock that night, the persulphate of iron was applied. At twelve o'clock on March 21, after administering the "A C E" mixture, the pins were removed, an incision made along the side of the umbilicus, and a ligature

passed around the cord before its exit from the abdomen. The wound was sutured and dressed with a pad of borated absorbent cotton and adhesive strips. This controlled the hemorrhage. The jaundice was more marked. The child, twice during the operation, showed the over-effects of the anæsthetic, and was with difficulty revived. There was no further bleeding. The child gradually grew weaker and died at two o'clock on the morning of March 23, thirty-eight hours after the operation. No *post mortem* was allowed, but close examination showed a small tear in the cord at its exit from the abdomen. The attending physician had administered calomel in small doses, paregoric and stimulants, had applied pressure, a new ligature, and persulphate of iron without effect.

The father was a bleeder, and the mother's health during her pregnancy was not good.

I trust obstetricians will give this subject more of their attention than they have heretofore done.

CONGENITAL SINUS OF THE URACHUS.[1]

BY A. VANDERVEER, M. D.,
ALBANY, N. Y.

Miss H. N., aged twenty, whose case I was requested to see with Dr. Du Bois, of New York, presented the following history:

Her mother stated that ten days after her birth the nurse discovered an unusual discharge from the umbilicus. The family physician's attention was called to it and he thought it was the result of delayed healing of the vessels of the umbilical cord. The discharge continued at irregular intervals, at times being very profuse, then quite subsiding; but for the past two years had been very distressing, in that the discharge had been more profuse and very offensive, also an unpleasant, sickening sensation so that she was unable to bear the weight of her clothing and was prevented from horseback riding or any other active exercise. From the parts above the navel there exuded at times a sebaceous substance quite sticky and very offensive in odor and which excoriated the parts somewhat. On May 20, 1886, patient was given an anæsthetic, and I found no difficulty in passing the probe down into the sinus some three inches towards the superior fundus of the bladder. The parts were carefully incised, the sinus thoroughly opened up, and I was quite surprised to notice its length, also the depth, as I was obliged to divide the tissues from the linea alba down to the sub-peritoneal space. The parts were thoroughly curetted, and lower portion brought together with sutures, and the upper part carefully packed with iodoform gauze and allowed to granulate. The union was perfect about the lower part of the incision, and the upper part healed gradually after about four weeks of treatment. The patient recovered, expressing later on, at the end of two or three months, the most marked relief from all her previous symptoms, and a complete recovery from the disagreeable discharge and odor that had annoyed her for so long a time. I do not know that there are any particular points of interest in the case except as to the previous treatment which had been carried on in the most intelligent manner possible, and was very thorough, but failed, so that the operation seems entitled to the credit of recovery of the patient.

These cases are somewhat rare and unique; very few are reported, yet it is fair to assume that a sinus of this kind is formed by the remnants of the urachus or allantois of fetal life. Cysts of the urachus have been reported occasionally, but this case did not partake of so formidable a nature as that.

[1] Read at meeting of Amer. Ass'n of Obstetricians and Gynecologists, Cincinnati, Sept. 18, 1889.

CASE OF HEMATO-METRO-COLPOS.

BY EBER L. ANNIS, M. D.,
LA PORTE, IND.

The article by Ferdinand H. Gross, M. D., on "Hematometra," published in the REPORTER, October 26, I read with peculiar interest, as I lately operated on such a case; or, more correctly speaking, one of hematometrocolpos.

On July 26, I was called to see a Mrs. F., of our city, married, about thirty years old, and the mother of five children, the youngest eight months old. She gave me the following history: For four months after the birth of her last child, which was normal in every way, so far as she knew, she noticed nothing unusual until the uterus began to enlarge and she suffered from severe bearing down pains. As these continued she sent for her family physician, who diagnosticated a tumor of some kind, and treated

her for some time for it. She, however, obtained no relief, and the pains becoming unbearable she sent for me. The pains were peculiar, in that they would begin at about two P. M. and last two or three hours, being, she said, "just like labor pains." They would then pass off, and she would rest well at night, but wake up to undergo the same torture on the morrow. She was pale and anemic, and to the eye presented the appearance of a woman in the sixth month of pregnancy.

On digital examination the finger penetrated about one and one-half inches, and was stopped by a dense cicatrix completely closing the vagina; above and below this a fluctuating tumor was felt. Upon examining the abdomen the enlarged uterus was found to extend to the umbilicus or slightly above. I diagnosed atresia vaginæ with hematometra, or rather, as Dr. Gross says, hematometrocolpos, and proposed an operation, which was gladly accepted. On the day following, assisted by my friend and colleague, Dr. R. O. Crandall, who after a thorough examination fully concurred in my diagnosis, I operated, chloroform being used as an anæsthetic. I separated the labia when the cicatrix came into plain view. Instead of using the trocar I divided the cicatrix with a bistoury making a small opening through which fully two quarts of a chocolate colored bloody fluid of a syrupy consistency escaped. I made no pressure over the uterus but allowed the fluid to gradually escape, this was accomplished in about thirty minutes. I then carried my dissection further, making a thorough division of the cicatricial tissue. The parts were then flooded and thoroughly cleansed with a hot carbolized solution and the patient put to bed. A pledget of cotton saturated with carbolized oil was introduced to prevent adhesion of the divided surfaces. There was no febrile reaction following the operation. The womb contracted well, and the patient made a rapid recovery. She menstruated sixty days after the operation and remains well to date. It seems to me that this case ought to impress the profession, as it certainly has me, with the importance of making post-partum examinations in all our obstetric cases to see that everything is all right, and that no lacerations, either of cervix, vagina, or perineum, have occurred. I regard this case of atresia as a result of a laceration of the vagina during labor and one clearly preventable.

Foreign Correspondence.

LETTER FROM INDIA.

Grant Medical College of Bombay. — Its Graduates.—Past and Present.

Bombay, India, September 24, 1889.

Since its establishment, this famous school has issued several graduates who have thrown brilliancy on the institution, spread fame in society, made names amongst their countrymen, gained glory throughout India, and whose early lives furnish a lesson for edification to many a medical sluggard of our times. From the list of old graduates we see two brightest gems "of purest rays serene," the brothers Dajees. Both brothers, Mr. Bhow and Mr. Narayan, have reached the very zenith of glory in their medical and social career. Their practice was, to say the least, overwhelming all throughout day and even night! Both of these eminent physicians combined native drugs in their English practice to a very great extent. They were the greatest and the profoundest botanists of India. They were scientific investigators of the virtues and properties of many native drugs. Due tribute is paid to Mr. Bhow's memory by naming one of the species of Boswellia after his name as *Boswellia Bhow Dajaania* and another species is named after Dr. Carter, the great medical investigator of India. The learning of these brothers Dajees was not confined to the medical sphere only, but they were great literati and eminent Sanskrit scholars. Both of them had become professors of Materia Medica and Botany in the Grant Medical College by force of their geniuses. They were University examiners, and sheriffs of Bombay. Mr. Bhow had a sudden paralytic stroke and died some time after that; and strangely enough his brother Mr. Narayan followed him after a year. On the same footing was Mr. Cutinho; he was just the beau ideal of a physician. From his tall figure, and a decent and grave style of his almost daily new dresses he used to impress on the mind of a stranger, that he was a physician. He had an extensively large practice, and was a very quick prescription writer. He died of some heart disease. Mr. Lisboa, a very old graduate, carries on a roaring practice since his graduation. The late Mr. Badhoorjee was also a dentist, and had a very considerable practice all throughout. Mr. P. M. Nicholson

is a very successful and accomplished physician; so is also Mr. F. Shapoorjee. The latter is an author of a work called "Management of Children." It is a splendidly got up work of a very practical nature. Mr. Dossabhai is a very old graduate and he is also an author of a work called "Every Man his own Physician." Mr. D. Jamasjee, at first a physician to an Indian prince, is now in private practice of a very extensive character. The late Mr. Khory was, with the late Mr. Badhoorjee, a pioneer of dentistry in Bombay. Many of the old graduates are now dead.

Leaving the old graduates, and coming upon the new ones, we see a roll of another set—a connecting link—between the old and the new graduates. In this roll we see Dr. R. N. Khory, a very accomplished physician, and the author of "Digest of Medicine." Mr. Gopal is a surgeon of considerable skill and ability. Dr. A. M. Kunte is a physician of a great name and fame. Since his graduation he has been an assistant surgeon to the government and Anatomical Demonstrator in the college—a very high honor indeed. Dr. Kunte was the first to acquire the degree of "M. D." in the University of Bombay. The rest of the graduates are either G. G. M. C., *i. e.*, Graduate Grant Medical College, or L. M. S., *i. e.*, Licentiate of Medicine and Surgery. Dr. Vicajee, a graduate of the University of Paris, was at first assistant chemical analyzer to the government and is an author of several pamphlets. So was late Mr. Khory, who used to issue a monthly called "Hygiene."

From 1874 commences the period of modern graduates. They have given a new direction to the medical profession. It is the joining of the Indian Medical Services. Many have joined it now. Some of them have been to England for acquiring degree there to practice in Bombay. Some have picked up some specialty, some are in the service of the native states. Others are in private practice by themselves. Native practitioners never think of partnerships. Some are doing well; others have to wait and watch their opportunity. The medical profession is overstocked. Some have got, through influence, certain dispensaries, and like other positions at a fixed salary. There are some, who are honorary surgeons to the government. Others have become teachers in the veterinary college. Their practice is not much to speak of, and cannot be compared to the overwhelming practice of the Dajee brothers or the roaring one of Mr. Lisboa; though, no doubt, that all of them earn just enough to keep them in a decent style. It is a matter of regret that none of the new graduates have made their name and fame as medical writers in journals and periodicals, or as authors, as we see in old graduates; though the facilities of journals and periodicals are far greater now than they used to be in the times of the old graduates. Among the new graduates, Mr. Kapadia is carrying on a splendid practice; so is Mr. E. F. Sethna; and no doubt, that both of them are full of promise and zeal. Mr. K. S. Engineer is a very skillful practitioner and an able teacher in Botany, Pharmacy, Materia Medica, and Chemistry in the Bombay Veterinary College. He has been an assistant surgeon to the government since last 12 years. Mr. J. P. Nicholson—the son of the celebrated practitioner, Mr. P. M. Nicholson, of whom I have said above—is a very simple and modest young practitioner, and doubtlessly he will in due course of time be just as much famous as his father is now, if not more than he. The same may be said of Mr. C. Motabhai; he is a very industrious and steady practitioner.

D. D. Bode, M. D., D. D. S.

LETTER FROM BERLIN.

Professor Brieger on Bacteria and Ptomaines.—Toxines and their Effects.—Cholera Bacilli and Cholera Colors.—Tetanin.—Auto-intoxication.

The powerful chemical actions of microbic organisms can be observed all throughout nature. The various fermentative processes, the changes in the soil after tilling, and the transformation of insoluble matters into solubles and, for plants, assimilizable ones, are all chiefly the work of micro-organisms. The study of the chemical relations of bacteria is consequently of eminent importance for the physician who desires to comprehend the symptomological aspects of diseases of parasitic origin. For it must be admitted that the mere mechanical propagation of microbes and the subsequent abstraction of albumin and oxygen from the blood, do not suffice to explain all phenomena connected with zymotic diseases. Bacteria being living organisms, it is clear that they cannot

exist except by feeding upon their surroundings, and that, on the other hand, they must excrete waste materials, which, in this instance, find their way into the circulation. The waste materials of a basic nature are clinically the most important ones, as they are able not only to damage but also to destroy the human organism. We distinguish between toxines, the more poisonous microbic excretions, and ptomaines, those of a less virulent nature. The number of chemically well-established toxines and ptomaines, which we have been enabled to prepare in a pure state is about forty-five, of which Professor Brieger has found nearly thirty himself. This number includes also the ptomaines which cause sickness en masse, such as is caused by deteriorated victuals. In the little clams (mytula edulis), of Wilhelmshafen, which a few years ago caused the death of many persons, Brieger found mytilotoxine, a body which hitherto has been found nowhere else, and which with chloride of gold forms a beautiful crystalline combination. Neurin and methylguanidin, however, which belong to the same order of toxines, can be found in various zymotic affections. The symptoms presented by a person poisoned by these little clams were a peculiar sense of constriction in the throat, mouth, and lips, burning in the extremities, numbness in the head, and a sensation as if the limbs wanted to fly upward. Every object lifted appeared of a wonderful lightness and seemingly tended to rise spontaneously. Suddenly the pupils dilated and great physical excitation set in, the patients ran about nervously until suddenly exhaustion and collapse supervened. Death was preceded by a profound fall of the temperature of the skin, violent vomiting and total loss of power. Five or six clams sufficed to cause severe attacks in adults. Some interesting experiments on animals were made with the water in which the clams had lived, and which, of course, after having been boiled did not contain any living bacteria, but only their toxine. The animals after taking this water soon began to move their heads to and fro, tried to escape under great excitement and dyspnœa, but did not get far, their legs suddenly becoming paralyzed. The muscles refused to work, and the animals sank down in utter exhaustion and perished during convulsions. Even after death the activity of the toxine does not cease, but being no longer impeded by the vital resistance of the cells of the organism it acts on the contrary, all the more violently and hastens the dissolution of the body. New toxines arise on the seventh day after death, particularly mydaleine, which even in small doses causes the death of animals with symptoms of violent diarrhœa, vomiting, and gastro-intestinal inflammation.

Of more general clinical interest are such toxines and ptomaines as arise from the actual virulence of certain bacteria. Staphylococci and streptococci, the microbic causes of pyemia and septicemia, present different chemical relations and consequently different manifestations of their destructiveness. From cultures of Koch's typhus bacillus we can prepare a toxine called typhotoxine, which injected into guinea-pigs causes paralysis of the voluntary muscles and increase of the salivary and intestinal secretions. The chemical virulence of Koch's cholera bacillus is particularly terrible, it generates, together with various special toxines, tetra- and penta-methylendiamin and methylguanidin.

This chemical action of the cholera bacillus explains the local intestinal irritation, the violent diarrhœa, the loss of the coagulability, and the varnish color of the blood, the frigidity and muscular cramps, and even the peculiar odor of the expired air of cholera patients. It is peculiar to the cholera bacillus that it abstracts from the soil on which it is artificially cultured certain substances which, after addition of concentrated sulphuric acid, produce a beautiful blue or burgundy-red fluorescent color. The colors thus produced are known by the name of cholera-blue, or cholera-red, and are genuine dyes.

From an arm just amputated from a tetanus patient we can prepare tetanin, a most virulent poison. Tetanin is a toxine excreted by Nicolaier's tetanus bacillus which originally exists in the soil, but, as Rosenbach has proved, can emigrate to the human organism. Besides this toxine the tetanus bacillus is capable of producing four other highly virulent toxines. Introduced into the animal organism the tetanus bacillus produces violent muscular spasms, cramps, and lock-jaw, with its usually fatal results. It is singular, that the introduction of toxines into the organism deprive the latter of its power to resist the entrance of dangerous or specific microbes. This, of course, constitutes a highly dangerous property of toxines. Hueppe has proved, that cholera bacilli, which could not enter the healthy organism, find their way

into the latter readily and in great numbers, if their toxines have been previously admitted. The experiments of Ehrlich and Brieger have also proven that the specific poison of typhus renders the system susceptible to the admission of the microbes of malignant œdema, which are harmless to a healthy organism.

Further studies on the chemico-bacterial poisons will probably decide whether the hitherto only hypothetical doctrine of the auto-intoxication of the human body can be regarded as a scientific fact. Much more desirable, however—and this is within reach of probability—would be the capacity to afford to the system immunity against the immigration of pathogenic bacteria by means of inoculation with their toxines. For as bacterial diseases are principally intoxications, the degree of susceptibility to infections is proportionate to the greater or lesser susceptibility of the individual to the poisons. Trials with inoculations of devitalized cultures of pathogenic microbes have been successful in chicken cholera, anthrax, typhus fever, etc. But there can be no definite results in this regard without the employment of the toxine prepared pure and chemically. Chemistry and internal medicine will have to join hands in order to attain results which shall benefit the suffering community at large.

PERISCOPE.

The Effect of Distension of the Abdomen on Circulation and Respiration.

The effects of pregnancy, ovarian dropsy, ascites, and other diseases, leading to great distension of the abdomen, in impeding respiration and disturbing the action of the heart, though there is little unanimity or precision in the opinions that are entertained respecting them, are generally admitted. Such affections are, indeed, of a chronic nature; the abdominal walls have time to yield, and the organs both in the abdomen and in the chest are enabled to accommodate themselves to the altered conditions; but we are not aware that any experiments have been undertaken to determine the effects of sudden distension of the abdomen in animals until the appearance of a paper by Dr. G. Heinricius, of Helsingfors, recently published in the *Zeitschrift für Biologie*. It is generally believed that in pregnancy there is marked increase in the tension of the systemic vessels, and that as a consequence the heart undergoes hypertrophy; but, although such statements are to be found in almost every gynecological text-book, the evidence on which they rest is extremely slender. In order to determine whether any obstruction to the circulation, which may exist in the uterine vessels in pregnancy would raise the general blood pressure, Dr. Heinricius first performed the very simple experiment of tying the aorta just above its division into the iliacs, and found that in four rabbits no change took place in the arterial tension of the carotids. Hence no effect was to be expected from ligature of the uterine arteries, nor from any such obstruction as might proceed from their distribution in the pregnant uterus and in the placenta. He next proceeded to ascertain by experiment the effects of distension of the abdominal cavity in the rabbit and cat. He employed a double canula, which was introduced through or at the side of the linea alba by a small puncture in narcotized animals; one arm of the canula was connected with a vessel containing normal saline solution at the temperature of the blood, and the other with a manometer. Arrangements were further made to record graphically the respiration and the blood pressure in the carotid. The respiratory and blood pressure curves were taken after each 50 or 100 cubic centimetres of the solution had been injected into the abdomen from the vessel, and the phenomena which were presented proved to be remarkably uniform. In all the experiments, which numbered fifteen, it was found that the abdominal cavity could be filled with a large quantity of fluid, so that the parietes were quite tight, without either pulse or respiration being materially disturbed. It was only after very great distension had been produced that the respirations became more frequent and deeper, the expiratory effort being particularly well marked. This dyspnœa was apparently attributable to the diaphragm being pressed upwards and the capacity of the thorax correspondingly diminished, so that mechanical obstruction to respiration was occasioned. The effect of this was that the accessory respiratory muscles were brought more into play, and the breathing became more and more thoracic in character. But these efforts soon became insufficient to compensate for

the defective action of the diaphragm. The respiratory centre became excited, but was soon paralyzed by the venous blood. The respirations underwent a change: they became first shallow and slow, then deeper; dyspnœa finally occurred, and the animal died. If we turn now to the effects of the distension on the circulation, we find that when the distension became considerable the pulse at first increased in frequency, then became fuller, afterwards less frequent, and before the death of the animal usually suddenly smaller. The arterial blood pressure first began to rise when the frequency of the pulse had considerably diminished, and then gradually fell as the pulse became smaller. Dr. Heinricius gives in the article we have alluded to numerous tracings which collectively show that the abdomen may undergo great distension without abrogation of the more important vital functions. The abdominal cavity of a rabbit can support in this way the introduction of 500 cubic centimetres of fluid without difficulty, and nearly a litre and a half of fluid can be further injected before dangerous symptoms supervene, clearly showing how extraordinarily yielding the abdominal parietes are, and affording a proof that it is not necessary to appeal to the slowness with which they are distended in pregnancy and in cases of abdominal tumor to explain the slight interference with the main functions of life that occurs in those conditions.—*Lancet*, Nov. 9, 1889.

North Texas Medical Association.

The next meeting of the North Texas Medical Association will be held in Gainesville, Texas, December 10 to 12, 1889. The meeting will be called to order promptly at 7.30 P. M.

In addition to the section work and other papers announced in this programme a number of papers and reports of cases have been promised.

The meeting gives promise of excellent scientific and social entertainment. In the last two years the Association has more than doubled its membership, and the interest in its ranks increases with every meeting. It is now established upon a firm basis and each of its more than two hundred members feels a personal responsibility and pride in laboring to promote its usefulness and further progress.

Every physician in North Texas who loves his profession, who desires his own advancement and respects ethical medicine, should attend the meetings of this Association, assist in the maintenance of its high character and encourage and foster its noted harmony.

Information on the subject may be had from J. T. Wilson, M. D., President, or Geo. R. Clayton, M. D., Secretary.

The Behavior of Germs in Milk, Butter, Whey, and Cheese.

Among the numerous labors of the Reichsgesundheitsamt, has been that of determining the behavior of certain germs of disease in various articles of food. Milk is one of the most common articles of diet; and one of the health-office collaborators, L. Heim, of Würzburg, has lately concluded a lengthened inquiry into the relations of the bacilli of tuberculosis, cholera, and typhoid-fever to it, and its products, whey, butter, and cheese. That milk is a favorite medium for dissemination of disease is well known; and Koch, among others, has shown that it is peculiarly adapted for this purpose. As regards cholera, the germs of the disease were still viable after remaining for six days in milk that had undergone no antisepticizing processes: in milk of the same character that had been kept in the ice-chest, on the other hand, no living bacteria were found at the end of three days. This part of the inquiry shows that cholera bacteria remain active in fresh milk the whole length of the time it is customary to keep it, and that they do not lose their dangerous quality for some days after the milk has become sour. The same germs were found active under some circumstances, even at the end of a month. In ordinary strong cheese they did not retain their viability over a day, neither did they in unripe cheese. The bacilli of typhoid were alive and capable of development in milk at the end of thirty-five days, but no longer so at the end of forty-eight days; in butter they remained active between three and four weeks, in cheese only three days, and in whey only during the first day. Tubercle bacilli remained capable of development for ten days in fresh milk; in milk gradually undergoing decomposition they lost their power in a period varying between ten days and four weeks. In butter, on the other hand, they retained their full power at the end of four weeks;

in whey and cheese after two weeks, but not after four weeks. The practical importance of the investigations is so obvious as scarcely to need pointing out; and their bearing on the use of milk, the preservation, carriage, preparation, and sale of it and its products, is equally obvious. Something has been done, much remains to be done, to stop the ravages of disease; and the labors of Dr. Heim are another step forward.—*Science*, Nov. 8, 1889.

Hypnotic Suggestion in Labor.

Professor S. Roman Cajal, of Barcelona, reports a case in which he abolished the pain of labor without in any way weakening the power of the uterine contractions by means of hypnotic suggestion. Ten days before his patient's sixth confinement was due, Dr. Cajal "suggested" to her, during hynoptic sleep, that her labor would be short, and that she would feel little or nothing of it. She obeyed the suggestion to the letter, and the dilatation of the os, the rupture of the membranes, and the expulsion of the fetus was all accomplished in less than half an hour. The patient was said to have had full consciousness of the contractions of the uterus, but without any sensation of pain, although the pulse was quickened and the breathing became labored, as is usual under the circumstances. When all was over she walked to bed with a firm step, and soon afterward asked for something to eat. She suckled the child on the second day, got up and resumed her domestic duties on the fifth, and was perfectly well within a fortnight from the date of lying-in. Dr. Cajal points out that the rapidity of the process in this case was not less noteworthy than the absence of pain; and this was the more remarkable inasmuch as her previous confinements had all been very long.—*British Medical Journal*, Nov. 9, 1889.

Operation on Gall-bladder.

On July 13, 1889, Dr. Terrier performed an operation which had never before been attempted in France. He established a permanent fistula between the gall-bladder and the duodenum in a woman whose ductus communis choledochus was obliterated, and who, being affected with extreme jaundice, presented very grave symptoms. Dr. Terrier has lately seen the patient, since the operation, and states that the jaundice has disappeared, the bile passes into the intestine, and the patient's health is excellent.—*Lancet*, Nov. 9, 1889.

Codeine and Morphine in Diabetes.

Dr. Mitchell Bruce has compared the effects of these alkaloids in two classical cases of diabetes. The observations extended over several months and were made with great care. The sugar in the urine was first reduced to a minimum by a strictly antidiabetic diet, and then one of the drugs was administered to both patients, and its effects on the sugar were noted. Phosphate of codeine was given subcutaneously, and the dose was gradually increased to more than twenty grains a day. After an interval on strict diet, acetate of morphine was given to both patients, up to as high as five or six grains per diem; of the two drugs, the morphine proved to be more efficacious, as under it the sugar was more completely controlled. Codeine is much more expensive than morphine, and large doses of it are necessary. Narcotic effects from morphine seldom presented themselves so long as the sugar continued to fall. Dr. Bruce found some difficulty in removing the last traces of sugar, and he suggests that in practice we should be satisfied with reducing the sugar to a small amount, rather than use the large doses required to free the urine from it completely.—*Boston Med. and Surg. Journal*, Nov. 14, 1889.

Thermo-Palpation.

It has been known for some time that there is a difference in the surface temperature of the body corresponding to the organs underneath—that is to say, the temperature is higher over the lungs than over the liver or the heart. From a communication published in the *Orvosi Hetilap*, one of the chief medical journals in Hungary, by Herr Jonás and Dr. Benezúr, it appears that this fact is available as a basis for a novel method of physical examination which may be styled "thermo-palpation." These observers say that it does not require any peculiar sensitiveness of touch or any special education to appreciate the difference of temperature on passing the fingers over the surface of the body from the situation of the lungs to that of the liver, and that patients

themselves and students who had not yet learned percussion were quite able accurately to detect the height of a pleuritic effusion by the difference of temperature. Diseased and healthy organs can be mapped out in this way by going over the surface, first, say, downwards and then upwards, when the line of demarcation will be distinctly felt. The general principle appears to be that organs containing air, such as the lungs and intestines, permit of greater surface warmth over them than more solid organs, such as the heart, liver, spleen, etc. Of course, instead of using the fingers, a differential thermometer may be employed, and much slighter differences may be recognized than is possible by the touch alone. The authors claim for thermo-palpation that it is so simple that it may be used by all practitioners as an additional method of examining their patients. Another advantage which occurs to us is that if the method is as trustworthy as they believe it to be, a good many sensitive patients will greatly prefer it to that of percussion, which, even when carried out with as much consideration for the patient as possible, is to some persons exceedingly distressing. Indeed, it is probable that some people avoid as much as possible sending for a medical man from the dread they have of being percussed.—*Lancet*, Nov. 9, 1889.

Simple Antiseptic Dressings.

The prepared antiseptic dressings now in the market are far from meeting all the requirements of the surgeon, and besides this, their preparation involves much labor and time, and often causes severe injury to the throat and eyes of those employed in their manufacture. Another, and most important point is, that the antiseptic properties of these dressings become impaired and lost after a certain time, and they are therefore of questionable value.

Dr. Oscar Bloch, of Copenhagen, in an address before the French Congress of Surgery, at its last meeting in Paris, October 12, proposed a new and simple method for preparing antiseptic gauze and cotton, the principal features of which was its universal applicability, its thoroughness, and the absence of any danger from poisoning.

Bichloride of mercury, he claimed, was a most dangerous drug to deal with, and even very weak solutions were capable of exerting powerful toxic properties. He therefore discarded its use altogether, in preference to a weak carbolic acid solution.

Regarding the preparation of antiseptic dressings he said that the surgical gauze or cotton coming into commerce should merely be aseptic ; its antiseptic property being imparted to it immediately before using it.

To sterilize gauze or cotton completely, it should be treated for some time in steam and afterwards dried at a high temperature. If the dressing, thus treated, is wrapped in packages of two thicknesses of filter paper, it will remain aseptic for an indefinite period, even although the outer covering becomes soiled.

To render the dressing antiseptic, it is only necessary for the surgeon to immerse it, for a few moments, in a three per cent. solution of carbolic acid.

In this way antisepsis is insured, danger of poisoning is avoided, and the expense considerably lessened.— *Gazette Hedomadaire*, Oct. 11, 1889.

Perspiring Feet.

Not long ago the relative values of various remedies for the treatment of perspiring feet were being tested by military surgeons abroad. A weak chromic acid solution seemed to yield the best results and was adopted for the German Army. Still, the acid solution is not entirely satisfactory, since it must be used most cautiously and, when applied to sore feet, not unfrequently gives rise to severe inflammation.

A simple and perfectly harmless preparation is the following :

℞ Talc . . . . . 10 parts
Alum . . . . . 2 parts

Mix, and dust freely and frequently on the feet.

This preparation has proved most efficacious and is largely used in the Swiss Army.

Saccharin.

Saccharin is said to be a powerful antiseptic. A solution of saccharin of a strength of 1 to 500 is an active germicide. A most efficient, and at once inexpensive antiseptic mouth wash can be made by preparing a six per cent. solution of saccharin in water. A teaspoonful of the drug to a pint of water would about make this proportion.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

EARLY DIAGNOSIS OF PREGNANCY.

All practitioners are aware of the importance of observations which tend to make the diagnosis of pregnancy, during the first three months, easy and positive. Within the past few years the resources of the diagnostic art have been increased by the addition of Hegar's and what, for want of a better name, may be called the "fat-bellied jug" sign of early pregnancy. These signs were discussed Editorially in the REPORTER, November 24 and December 29, 1888. The bluish or violet discoloration of the vagina, as a diagnostic mark of pregnancy, and its true value, have also been more fully elucidated through the labors of Chadwick and others. With a thorough appreciation of these signs the practitioner who is skilled in making the bimanual examination should be able to make a very certain, if not a positive, diagnosis of pregnancy after the end of the sixth week in a large proportion of cases. This proportion depends mainly on the examiner's skill, and also on the willingness of the patient to submit to examination. An unruly patient, who tosses about during examination, or who vigorously contracts the abdominal muscles, can often prevent even an expert from drawing more than a suspicion from his examination, as to the conditions present. It is difficult also to arrive at a satisfactory conclusion from the examination of corpulent persons, no matter how willing they may be. Furthermore, pregnancy may be complicated by vaginitis, unilateral salpingitis, or other pelvic inflammation, rendering an examination so painful as to prevent accurate conclusions being drawn. And when we add to these the women who will not submit to an examination, or who are not asked to, it is plain that, in spite of the great value of the signs named in the diagnosis of early pregnancy, there remains a certain percentage of cases, in which these signs are either not available, or are insufficient.

In a contribution to the *Journal of the Amer. Med. Association*, Dr. Llewellyn Eliot discusses the pulse-test, or Jorissenne's sign of pregnancy. Dr. Eliot states that a remarkable constancy in the pulse-rate exists during pregnancy, no matter what position the gravid woman assumes. He tabulates nineteen cases in which this point was noted. The variation in the pulse-rate, taken with the subject standing, sitting and lying, was usually from two to four beats per minutes, and the extreme variation was six beats.

According to Flint, the pulse in woman is: standing, ninety-one; sitting, eighty-four; lying down, eighty. This is the average of a large number of observations. He states, however, that in some women the attitude hardly affects the pulse-rate. The pulse sign of pregnancy is not generally employed in the diagnosis of that condition. Nor, at first thought, does it seem that the test will prove generally reliable.

The difference in the variation for the pregnant state, as given by Dr. Eliot, and that of the non-pregnant state is not great; and, as the pulse-rate is liable to be altered at any moment by emotional or other influences, the chance of error is clearly great. However, theoretical considerations should have little weight in a practical matter. This sign is certainly worth looking for; and, should further observations demonstrate its reliability, it will prove of very great value indeed, especially in the class of cases in which the more usual methods of diagnosis are not available.

THE CENSUS AND VITAL STATISTICS.

The last meeting of the American Public Health Association, which was held in Brooklyn, October 22–24, was one of great importance; and the papers read of a very high degree of interest.

Foremost among these was a paper read by Dr. John S. Billings, on the subject of "The United States Census in its Relation to Sanitation." Dr. Billings emphasized the importance of the collection of vital statistics, which many men do not regard as so important as other work in behalf of public health. In order to convince the press and the community that the work of a board of health is necessary, he said, we must produce constant, undeniable evidence; and this evidence must be mainly death-rates, to which should be added all the sickness-rates obtainable. To do this there must be a complete registration of deaths and births, and an enumeration of the whole population. Before the Association meets again, the eleventh United States census will have been taken, and its methods and results are of great interest to all sanitarians. One of the most important questions to be settled before the census is taken is, "What shall be the boundaries of the special districts of the city for which a separate statement of the population is desired?" In some cities the wards form fairly satisfactory districts for the purpose. Where this is the case it makes the problem very easy; but in many cities these divisions bear no proper relation to different sanitary conditions; therefore in about a dozen of our large cities it is proposed to make a systematic division of the area into sanitary districts having special relations to altitude, character of habitations or of population, etc., and to have special death-rates calculated for each of these districts. This, Dr. Billings says, is being done, in conference with the health authorities of these cities, and it is hoped that in this way some very interesting data will be obtained which will serve as a foundation for sanitary work in the future. He advocated also the plan of charging all deaths occurring in hospitals to the ward or district of the city from which the patient was taken to hospital. In cases of death of colored persons it is very desirable that it should be stated whether the decedent was black or of mixed blood, such as mulatto or quadroon; since one of the most important questions in the vital and social statistics of this country relates to the fertility, longevity, and liability to certain diseases of those of partly negro and partly white blood. For all cities of ten thousand inhabitants and upward, it is proposed to collect as complete information as possible with regard to altitude, climate, water-supply, density of population, sewerage, proportion of sewered and non-sewered areas, and other points bearing on the healthfulness of the place which permit of comparison with the death-rates. The cordial co-operation of all physicians and sanitarians is solicited in making the data of these reports accurate and complete. It is desired to make these vital statistics an unanswerable argument in favor of systematic public sanitary work and of the granting of State and municipal funds necessary for maintaining such work.

We most heartily commend these views of Dr. Billings to the attention of our readers. Most of them have probably had reason to regret the exceedingly great imperfection in

the methods of collecting and tabulating vital statistics in this country which are now in use; and it is to be hoped that they will not fail to appreciate the present opportunity of co-operating with so able and so devoted a sanitarian as Dr. Billings in bettering the existing state of affairs. It is fortunate that the Government has placed so competent a man at the head of this department of census work, and we trust that the readers of the REPORTER will neglect no means of aiding him in making it an important help for many years to come to all who are interested in promoting measures for improvement of the public health.

EXPERIMENTAL INVESTIGATION OF HYDROPHOBIA.

In the matter of the disease known as hydrophobia there are uncertainties and contradictions of observation and experience which makes it still the most obscure subject in the whole round of medical science. A careful comparison of the symptoms ascribed to it in ancient and modern writings, with those observed in a number of better understood disorders, compels the conviction that many cases reported as hydrophobia ought to be classified differently. The commonly held ideas in regard to its symptomatology bear the marks of ignorance and superstition, and its pathology is—we may say—utterly unknown. The ablest students of the subject are agreed that there is nothing characteristic and peculiar to be found in the bodies of men or of animals dying of rabies or hydrophobia; and in this, as Bollinger has pointed out, in his chapter on the pathological anatomy of hydrophobia, in Ziemssen's Cyclopedia, we are in the same state of ignorance as we are in regard to the pathological anatomy of epilepsy, tetanus and chorea.

It is not surprising, then, that many medical men hailed with delight and accepted with alacrity the suggestion of Pasteur that an absolute diagnosis of the presence of genuine hydrophobia—or rabies humana—can be founded upon the effect of inoculation of the substance of certain parts of the body upon the bodies of previously healthy animals.

Confidence in this method is founded upon two sorts of reasoning: first the deductive, which characterized the original announcements of Pasteur; and second, the inductive, which characterizes his later work and that of his followers. The former may have been as correct as it was unquestionably brilliant, but the latter has more elements of stability and deserves more consideration. The former met with as strong antagonism on the part of a few critics as championship by many admirers of the eminent savant who propounded it; the latter likewise has been, on the one hand, opposed at every step, and, on the other, endorsed and commended as it went along. The truth in regard to it cannot be said to be incontrovertibly established as yet; still, the evidence which will ultimately settle its correctness or incorrectness is accumulating; and we may be nearer a final determination than appears.

One thing, at least, is lacking before the end can be obtained, namely the demonstration that nothing beside the so-called "virus" of Pasteur is capable of producing the manifestations usually attributed to experimental rabies. This is necessarily very hard to demonstrate, because, no matter how many substances may be tested in this way, it is still possible for a caviller to claim that something yet untried might produce the same effects; and it must be admitted that heretofore no systematic attempt has been made to perform so extensive a series of experiments as would exclude any large number of substances, normal or abnormal, from the category of those which may produce phenomena analogous to those produced by Pasteur's virus of rabies.

The attention of our readers has already been called, simultaneously with their an-

nouncement, to the experiments of Spitzka with various irritating materials, and to those of Peyraud and Trasbot with tanacetic acid —in regard to the latter of which the most surprising ignorance is manifested by certain experimenters and authors.

The best contribution to filling this gap in the argument of Pasteur and his followers, with which we are familiar, is that of Dr. Arnold Paltauf, of the University of Vienna, as reported in a paper in the *Vierteljahresschrift für Gerichtliche Medicin*, October, 1889. Some familiarity with the literature of hydrophobia warrants the statement that the paper of Dr. Paltauf is one of the most admirable contributions to it which has ever appeared. What concerns us most at present, however, is the fact that he is thoroughly convinced of the reliability of the "inoculation test" of the genuineness of a suspected hydrophobia. In corroboration of his opinion, he cites a number of experiments on rabbits with fragments of medulla oblongata taken from the bodies of individuals who had died of epilepsy, acute delirium, acute mania, delirium tremens, tetanus and eclampsia. None of these experiments resulted in manifestations similar to those produced by inoculation with the virus believed to be that of hydrophobia, or rabies.

Striking as these results are, it may be that they are not as conclusive as they appear; for other experimenters may have a different experience. This would not be surprising; for contradictory observations are not unknown in experimental pathology. Paltauf himself gives some space to combating the claims of Shakespeare, in the *Centralblatt für Bakterien-und Parasitenkunde*, 1889, Band II, No. 18, that experimental tetanus can be produced by inoculation with the medulla of tetanic subjects; and it is possible that his own negative results with the disease named above may be opposed by positive results obtained by other experimenters.

The length of this Editorial precludes further discussion at present of the subject in hand; but we would be glad if it attracted attention to a matter about which we have some decided opinions, and which invites to careful and unbiased study. Justice to the truth demands that such excellent work as Paltauf has done should receive due recognition; and no one who seeks the truth should hesitate to recognize its importance. It need not be taken as settling the very serious question of the nature of hydrophobia; but it deserves all the respect which is accorded by fair-minded men to careful and conscientious scientific investigation.

INTEGRITY IN MEDICAL COLLEGES.

It is a sign full of good omen that just now the attention of the members of the medical profession in this country is being called, in a number of different places, to the shame of dishonesty. For some years past there has been an apparent indifference in the profession to the questionable methods of some medical journals and medical schools, and, indeed, of certain medical practitioners. But now there seems to be a sort of awakening, and from various directions indications appear that it is only a temporary and seeming success which can be secured by ways which honorable men do not approve. It is well, we think, that responsible medical journals should, when occasion offers, express the sentiment of the best part—and by far the greater part—of the profession, so that those who might mistake its silence may understand clearly that the way to attain true success is to avoid not only the committal but also the appearance of evil. Not long ago, one of our contemporaries pointed out the practical deception in the way in which a medical school printed the names of its graduates and matriculants, so that a false impression might be made as to their numbers. This is a fault which may not be very serious in itself, and one which admits of a plausible explanation; but it shows the natural inclination

to swerve from the path of exact rectitude when there is some temptation to do so. Instances of like frailty might be cited from a number of medical schools in this country, but at this time a single case is enough to suggest the thought we wish to present, and to justify our pointing to the general sentiment of the profession, which, if properly appreciated, will no doubt prove sufficiently strong to correct a number of errors which now exist, so that these fountains of instruction may furnish also examples of general management and of personal character which their alumni may not fear to cite as ideals of what such institutions should do and be.

THE WATER-SUPPLY OF PHILADELPHIA.

It is with great regret that we note the fact that, on October 29, seven physicians of Philadelphia who are well known to their fellows in the profession and to the community, addressed a letter to the Board of Health urging it to adopt a resolution requesting the citizens to "boil all drinking water." The reasons given for making the alarming suggestion are so vague and expressed in such general terms that it is not easy to pick out a definite assertion for examination; but the burden of the complaint seems to be that the present water-supply of Philadelphia is injurious to the health of the citizens.

This the signers of the letter indicate by using the expression "the acknowledged unwholesomeness of our water-supply." In doing so, however, they are simply joining their names to those of others who have brought an unfounded accusation against the water of this city, and who have been unable to justify their statements by any evidence of a scientific character. Whatever may be true in regard to defects in the water-supply of Philadelphia, one thing is certain, and that is that the persons who have thought it dangerous to health have found it much easier to say so than to prove it.

As a large part of the complaint about the Philadelphia water is supposed to be justified by the prevalence of typhoid fever it is interesting to note that the *Ledger*, November 29, 1889, contains a carefully prepared editorial, showing that typhoid fever occurred relatively less frequently in Philadelphia from 1880 to this time than it did in the decade from 1860 to 1870; while the known and estimated mortality from typhoid fever in 1889 will be almost exactly the same, with a population of nearly a million, as it was in 1865, when the population was about six hundred thousand. This statement will not surprise any person familiar with the vital statistics of Philadelphia; but it places in a strong light facts which seem to be unknown to some of our medical men.

The facts as just given are of great significance, for they present the case of typhoid fever in Philadelphia under conditions not only of increase in the population of the city but also of increase of population and of assumed pollution in the whole Schuylkill Valley.

The old adage *ex uno disce omnes* applies to the present discussion. It is with no intended disrespect to the signers of the paper referred to above that we call attention to the fact that eminence in the medical profession should make those who enjoy it especially careful in expressing opinions on subjects of which they have only a general knowledge.

No careful study of the water-supply of Philadelphia has ever been made which furnished any good evidence that it is unwholesome or unfit for drinking without boiling.

This fact may not, and does not, affect the large and important matter of getting, if possible, still more agreeable drinking water; but it suggests that regard for their reputation for sagacity should prevent representative medical men from making assertions which neither they nor anybody else can establish when challenged to do so.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

A TREATISE ON THE SCIENCE AND PRACTICE OF MIDWIFERY. By W. S. Playfair, M. D., LL. D., F. R. C. P., Professor of Obstetric Medicine in King's College, etc. Fifth American, from the Seventh English edition. With notes and additions by Robert P. Harris, M. D. With five plates and two hundred and seven illustrations. 8vo, pp. xxv, 671. Philadelphia: Lea Bros. & Co., 1889. Price, cloth, $4.00; sheep, $5.00.

Playfair's Obstetrics is so well known to English readers, that it is unnecessary to draw attention to its special features in detail. The fact that it has passed through seven editions in Great Britain and five in this country is ample evidence that the profession appreciates its compact form, pleasing style, and its thoroughly practical exposition of the subject. The present edition has been quite fully revised, especially by the American Editor, whose contributions to earlier editions have been in great part re-written. The author could have still further improved the work by more extensive revision.

The amount of space devoted to the subject of abdominal palpation is entirely inadequate, and the student will be utterly unable to obtain results in diagnosis from the teaching here presented. The author speaks of autogenetic and heterogenetic infection in puerperal septicemia. This is not in accord with modern views, since it is now held that all infection must come primarily from without. But it accords with what is now well known to be true, namely, that the vagina contains large numbers of micro-organisms, which doubtless at times prove the source of infection in septicemia—no other infectious material reaching the puerpera. The section devoted to antiseptic and germicidal agents could be improved upon by insisting upon the evil as well as the good which may result from the use of these substances. The use of boiled water as a means of cleanliness is not appreciated. The chapter devoted to pelvic cellulitis and pelvic peritonitis does not reflect the opinion held by certain abdominal surgeons that these inflammations are simply complications and secondary effects of tubal and ovarian disease, as was held by Bernutz many years ago. Ante-mortem and post-mortem sections must settle this question. The truth probably is that, while salpingitis is a much more important and frequent cause of puerperal peritonitis and cellulitis than is taught by the author, these diseases are not uncommon in puerperæ, the route of infection being other than the Fallopian tubes.

The work of the Editor has added much to the value and freshness of this book, especially in the sections devoted to the Cæsarean Section and allied subjects. We can but think that no little part of the interest now felt in the Cæsarean Section is due to the work of Dr. Harris, in studying the history of the subject, and especially the causes of success and failure attending this operation. In spite of the lack of thorough revision by the author of this book, it is undoubtedly one of the best and by far the most readable of the shorter treatises on obstetrics.

—The suggestion is made that New York might get out of its electric execution dilemma by putting condemned murderers at work as telegraph linemen in New York City.

Correspondence.

A Correction.

To the Editor.

Sir: In the Reporter of November 30, 1889, you published a review of my little work entitled "Questions and Answers on the Essentials of Medical Chemistry."

While thanking the reviewer for endeavoring to point out some errors and omissions, I feel called upon to revise his would-be corrections. He states that "on page 41 Cl is called a heptad and N a diad." The latter is simply a typographical error, and would arise by its third position in a progressive series; and I trust that my reputation as a chemist insures me against being thought capable of presenting nitrogen in that role.

As to chlorine being a heptad, I would like to ask my reviewer if, besides being a monad, triad and pentad, it is not also a heptad; or: if Cl, I and Mn are not septivalent, which elements are septivalent, or how can septivalency be illustrated otherwise?

As to the supposed error pointed out by my reviewer of giving the specific gravity of the NaOH solution in Fehling's test as 1.34, when according to him it ought to be 1.14, it is probably due to the fact that my reviewer did not read my formula closely enough. I give only 100 c.c. NaOH solution for the 500 c.c. alkaline Seignette solution instead of the often used 300-350 c.c. solution of the specific gravity of 1.14. Fehling, and after him Soxhlet, who has so thoroughly gone over this field, give no specific gravity for NaOH solution in Fehling's test but state that in one litre of the solution (both alkaline and cupric) there should be about 50 grammes NaOH (see Fresenius' Analysis). To give 1.14 as the sp. gr. for 100 c.c. NaOH solution to be used would yield a reagent decidedly deficient in alkalinity. It does not matter, therefore, what the specific gravity of the NaOH solution used may be if the amount is in proportion to the total NaOH required. The formula of Fehling's solution published by me is *correct*, and is used and advocated by many of our most prominent physiological chemists. It may be found in T. Cranstorm Charles' celebrated work on physiological and pathological chemistry, and in many of the later German works, as well as those by some American authors, and is that used at the chemical laboratory of the Jefferson Medical College.

I offer this simply as a correction for what might have led your readers to think wrong.

Yours truly,

L. Wolff, M.D.,
Demonstrator of Chemistry, Jefferson Medical College.

Philadelphia, Dec. 3, 1889.

Notes and Comments.

Iodide of Potassium.

At a meeting of the French Academy of Medicine, Dr. Germain Sée read a very interesting paper on "How Iodide of Potassium acted on the Heart." He commenced by saying that although ten years had elapsed since he introduced into medical practice the treatment of asthmatic and cardiac affections by iodide of potassium, yet nobody has ever inquired how it acted in such cases. All the actions of the two salts were not the same; that of potassium excited the heart and the vaso-constrictor nerves, and consequently raised the pressure of the blood, while the iodide of sodium did not do this. Injections of both salts into dogs were made, and the blood pressure in the femoral and carotid arteries recorded. The injection was made into the saphena vein. With the iodide of potassium the blood pressure arose immediately several centimetres and remained stationary for a considerable time. At the end of an hour a gradual descent took place. The vaso-constriction is to be attributed to the potassium, and the vaso-dilatation to the iodine. Iodine usually provokes a congestive condition of the bronchial mucous membrane, this being due to the vaso-dilatation of the vessels. The first and principal of these therapeutic congestions is that which occurs in the respiratory organs, producing a veritable hyper-secretion. Thus it results that the viscous and adherent exudation of mucus which characterizes the troublesome expectoration of asthmatics is softened and replaced by a liquid secretion, and consequently the air penetrates more freely and the dyspnœa ceases so soon as the iodine commences to act. The cardiac organ is materially strengthened, the circulation of the coronary arteries receives a considerable impulse as well as in the whole arterial system, as a result of its action on the nervo-muscular system and the myocardia in particular. The phenomena due to the iodine soon appear, in which are manifested the general vaso-dilatation, and, as a consequence, the heart, in order to propel the blood through its own arteries and into its own tissues, is no longer obliged to furnish the same amount of work as in the former state, as the tonicity of the arteries, the natural obstacle, is modified. Hence the organ, far from being depressed and weakened, beats with renewed energy and strength, and the sphygmograph indicates a full and strong pulse. For a long time Dr. Germain Sée has recognized the utility of iodine in several heart affections, and only in cases where it determined hemorrhage or gastric troubles did he refrain from prescribing it. When the dyspnœa is pulmonary from venous congestion, or œdema, iodide of potassium is given with best advantage. The cardiac affections which are mostly benefited by this treatment are adiposis, fatty degeneration, weakened heart, cardialgia, nervous or organic irregularity of the heart. As to the aneurism of the aorta, iodide of potassium is the only remedy that gives real satisfaction. In conclusion the author said iodide of potassium was the true cardiac agent. Far from being a depressor, it was particularly useful in mitral lesions with debility. It raises the energy of the heart and the vascular pressure. Then, in dilating the arteries, the flow of blood is faciliated and the organ recovers its contractile powers. — *Medical Press and Circular*, October 23, 1889.

Creasote in Phthisis.

The literature on this subject is increasing. From a paper emanating from the Greifswald Klinik of Professor Mosler, we learn the method in which it was employed in a comparatively large number of cases, and the results obtained after careful observation. The patients were fifty-three in number, and the mode of administration was by capsule, and in a mixture with tincture of gentian. The dose was small at first, and there were but few complaints of its disagreeing. Its reported effect in reducing the temperature was not confirmed. Thirty cases distinctly improved under its use, and in twelve of the number the improvement could not be put down to any other cause than the drug used. In the lighter cases of hemoptysis it had an action apparently favorable, as the expectoration became less

and the hemorrhage ceased. Bronchial secretion and cough constantly diminished, but the sputum still contained tubercle bacilli. The improvement was the greater in proportion to the quantity of creasote borne. If the results in far advanced phthisis were nil, the drug was certainly to be recommended in commencing disease, and in those chronic cases which had not advanced too far.

Professor Sommerbrodt, of Breslau, treats of the same subject in the *Therap. Monatsch.*, July, 1889. He maintains that creasote is an anti-bacillery remedy of the first order. Guttmann affirms, that in order that the body may be in a state of perfect disinfection, more than one gramme of creasote must be in circulation at once. Sommerbrodt has given this daily dose to hundreds of phthisical patients. One patient took nearly nine ounces of creasote, and thirty-five ounces of Peruvian balsam between September 1, 1888, and the beginning of June, 1889. The result was extraordinarily favorable. The chief thing to be careful about, is to give the medicine on a full stomach. The more creasote is borne the better the effect. Notwithstanding the experiments of Cornet which showed that the incorporation of creasote did not hinder the growth of the bacilli, this does not impair the professor's faith in the direct antagonism of creasote to tubercular infection. Small doses are of no value, but fifteen to twenty grains given daily for months together can alone produce any effect.—*Medical Press and Circular*, Oct. 30, 1889.

Extra-Genital Syphilis in Moscow.

Professor Pospêloff, of Moscow, has recently published an account of the extra-genital syphilis which he has met with, amongst the working-class population in Moscow. He has seen a great many more of these cases amongst women than amongst men, the actual figures being fifty-two male and 146 female cases. The most common seat of these non-venereal sores is the mouth. This kind of infection is mainly due to the dirty habits of the people, who habitually eat together out of the same vessel, and even with the same wooden spoon, which, if any of the persons using it are syphilitic, soon becomes a fruitful source of infection. Again, it is found that in small factories and sewing shops the workwomen very frequently suffer from extra-genital syphilis, showing that cleanliness and sanitary supervision are very defective.—*Lancet*, Nov. 2, 1889.

Toxic Nephritis.

A discussion took place at the recent Congress of the Italian Society of Medicine, upon Bright's diseases, in which the views of Semmola, as to the dependence of albuminuria upon the malassimilation of proteids were in part adopted by M. Rattone, who further declared that nephritis is not invariably due to a primary renal lesion, but to a transmission, through the kidney, of substances which have a toxic action and produce inflammation of the vessels of the connective tissue and epithelium. In the majority of cases acute nephritis is, he thinks, due to the introduction of an organic (microbe or its product) or inorganic poison.—*Lancet*, Nov. 9, 1889.

Death from Rabies after Treatment by Pasteur.

A sad case is reported in the *London Med. Recorder*, Oct. 21, 1889. A man was bitten by a dog on March 3, 1887. The dog was at once killed, an autopsy was held and the animal was pronounced to have been suffering with rabies. The man had the wounds touched with nitrate of silver, and then went to Pasteur's Institute, where he was treated and later discharged as cured. On May 20, 1889, two years later, Dr. Desquin was called to see the man, and found him suffering with symptoms of hydrophobia. In spite of all that could be done the poor patient died in two days.

High Temperature in Children.

It is a well-known clinical fact says Dr. W. J. Tyson, in the *Lancet*, Oct. 19, 1889, that the body temperature changes quickly in children, and without this knowledge we should be constantly alarmed. He refers to cases to which one is called at night, with a temperature of 102° to 104°, a pulse varying from 100 to 150, and the respiration, as a rule, not increased in the same ratio. On visiting the child the next morning the temperature is normal, or even subnormal, and the child apparently perfectly well.

Some men will say that the medicine ordered, such as tincture of aconite, in drop doses frequently, a cooling saline, or a little gray powder, has been the means of lowering the heat. This may or may not be so. The most common cause of the elevation of temperature is probably some error in diet; another common cause is a sort of sunstroke. Children, in playing, constantly throw off their caps and hats, and are exposed to the sun for many minutes.

Digitalis in Pneumonia.

Since 1883, Dr. Petresco has treated all cases of pneumonia by means of large doses of the infusion of digitalis, one to three drachms of dried leaves to seven fluidounces of water and one and one-half fluidounces of syrup; dose, a tablespoonful every half-hour. The results have been eminently satisfactory, the attack generally aborting by the second or third day, and the physical signs disappearing altogether at the end of the third. In certain cases twenty-four hours have sufficed to enable the patient to return to work. The tolerance and non-poisonous effects of the drug were proved by 755 observations.—*London Med. Recorder*, Oct. 21, 1889.

Association of American Anatomists.

The second meeting of the Association of American Anatomists will take place in the Biological Department of the University of Pennsylvania, December 26, 27, and 28. This meeting is expected to be one of considerable interest as it is the first one since the organization of the Association; and is an attempt to unite the anatomists of this country, which it is hoped will prove successful and profitable to the development of this branch of science. The members of the medical profession are invited to attend the meetings.

Salol in Burns.

Grätzer recommends a mixture of from 2 to 3 parts of salol with 50 parts of starch as an application to inflamed and painful surfaces, bruises, burns, and painful skin diseases of all kinds. The relief is said to be great and very prompt. The remedy is simply dusted on the surface.—*National Druggist*, Nov., 1889.

Cocaine.

Dr. Szumann, in the *Therapeutische Monatshefte*, suggests some limits within which cocaine may be used with safety, a point of great practical interest. With doses for adults of one-half to three-fourths to one grain subcutaneously he saw no untoward effects; one grain, however, is adapted only to robust individuals. Some patients will, of course, bear very large doses, among them certain opium takers, who have used as much as seven to thirty-seven grains daily, though one may get toxic symptoms in such patients from an injection of one and a quarter grains.

With nervous patients, and also with those having cardiac disease, as well as those inclined to cerebral congestion, large doses of cocaine may prove dangerous on account of the marked effect on the heart and circulation. Where injections of cocaine are made about the head, not more than half a grain should be used.—*Boston Medical and Surgical Journal*, Nov. 14, 1889.

Blockley Hospital.

The third annual banquet of the Association of ex-resident and resident physicians of Blockley Hospital, was held December 3, 1889, at the Hotel Bellevue, in Philadelphia. The attendance was large, and the cheer was very good. The association elected Dr. Alfred Stillé to be President, Dr. E. R. Stone to be Secretary, and Dr. J. B. Walker to be Chairman of the Executive Committee.

Creolin Irrigations in Dysentery.

The encouraging results obtained by Kortum, Neudorfer, and Esmarch in the treatment of dysentery with irrigations of a creolin solution, have recently led Dr. Nicolaï P. Ossowsky to test its efficacy in a large number of cases of the disease occurring in soldiers. His experiences with the drug, which are reported at length in the *Gazette Hebdomadaire*, October 4, 1889, were most satisfactory. In every instance the treatment was followed by a speedy and complete recovery. In many cases all symptoms of the disease disappeared in two or three days; in few only was it necessary to continue the treatment for a week.

The irrigations were made two or three

times a day, according to the severity of the case, and a one-half per cent. solution of creolin employed. Ossowsky used a long rubber catheter in giving the irrigations so that high portions of the bowel could be reached.

Dr. Kolokoff, of St. Petersburg, has likewise used the drug in a large number of cases with equally happy results.

Nitrous Oxide and Ether.

A contributor to the *Lancet* says that the nauseous flavor and the sense of suffocation from ether can be entirely done away with by the use of nitrous oxide, and its inhalation made more agreeable than even that of chloroform, while the patient quickly becomes unconscious without the struggling so common with chloroform. The writer goes on to say, he has not yet found a single patient who has once inhaled ether preceded by nitrous oxide complain of suffocation, or object to take it again on the ground of its unpleasantness.

Mouth Washes.

Hygiene of the teeth is as important as that of other parts of the body; and prophylaxis in this direction will prevent decay as well as keep the teeth clean and the breath sweet. Monte, in the *Deutsche med. Wochenschrift*, October 31, 1889, gives the two following formulas for prophylactic mouth washes:

℞ Acidi borici . . . . . gr. xxxviij
Aquæ destillatæ . . . . . f℥vij
Tincturæ Myrrhæ . . . . . ♏xxxxviij
M.

℞ Sodii salicyl. . . . . gr. xxxxiij
Aquæ destillatæ . . . . . f℥vij
Tincturæ Myrrhæ . . . . ♏xxxxviij
M.
Sig. Wash out the mouth several times daily with either of the above formulæ.

Codeine in Abdominal Pain.

The fact that many practitioners still prefer opium to morphine in the treatment of abdominal pain, led Lauder Brunton to question whether some other alkaloid than morphine was not more powerful in cases of this sort. Barbier, in 1834, found that codeine had an especial action in lessening pain from irritation of the solar plexus, while it did not disorder digestion, and rather aids the action of the bowels. Brunton concluded from these and other experiments that codeine is likely to be of value in relieving abdominal pain, and has employed it with success especially in painful affections of the intestine and lower part of the abdomen. It is particularly valuable where morphine is to be avoided on account of the condition of the heart or lungs, or where it is desired not to interfere with the action of the bowels, on the other hand, where there is much diarrhœa it is not so serviceable as morphine or opium, because it does not lessen peristaltic movement. The dose employed is half a grain in pill.—*Boston Med. and Surg. Journal*, Nov. 14, 1889.

Treatment of a Cold.

Dr. S. Wilson Hope, in the *British Med. Journal*, Nov. 11, 1889, says that 20 grains of salicylic acid, given in liq. ammon. acet. three or four times a day, will so far control a common cold that the aching of the brow, eyelids, etc., will cease in a few hours, while the sneezing and running from the nose will also abate, and will disappear in a few days, and, more fortunate still, the cold will pass off, and not finish up, as is customary, with a cough.

Internal Urethrotomy in Cuba.

Dr. Ignacio G. Plasencia, in his inaugural address on the occasion of his admission to the Cuban Royal Academy of Medical, Physical, and Natural Sciences, gives an account of 133 cases in which he has performed internal urethrotomy. He states that from his experiences strictures treated by cutting from within do particularly well in Cuba—a good deal better than in Europe,—the climate appearing to favor this operation in a remarkable manner; urethral fever being much less frequent, and, when present, less severe, than is usually found to be the case after urethrotomy in Europe. None of his cases were complicated by purulent infection; and extravasation of urine occurred in five only of the oldest and tightest strictures, which were not operated on as soon as they ought to have been. The instrument preferred by Dr. Plasencia is the urethrotome of Maisonneuve. — *Lancet*, Nov. 9, 1889.

Cooling the Body by Spray.

Dr. S. Placzek, in the *Lancet*, Nov. 9, 1889, says that he has applied the spray for the purpose of reducing febrile temperatures in human beings. In the case of a man suffering from phthisis, whose temperature was high, he found that by spraying about a pint of water at between 60° and 70° F. over his body the temperature fell to normal, and continued so for several hours. Again, a similar method was satisfactorily applied in the case of a girl with diphtheria. In the healthy human subject the spray lowered the temperature nearly 2°, and in animals which had been put into a condition of septic pyrexia by injections of bacteria the temperature was reduced to normal by the spray.

Funeral of Philippe Ricord.

The funeral ceremonies of the great specialist were among the most impressive that Paris has seen for many years. Ricord's historic house in the Rue de Tournon was beautifully draped, and the large courtyard converted into a *chapelle ardente*.

Military honors were rendered to the deceased doctor as a Grand Officer of the Legion of Honor. The cortège, which was preceded by a military band playing Chopin's funeral march, was very long, and in it were represented various orders of nurses and religious sisters of the Parisian hospitals, the officers of a number of institutions and orders, and a very large number of the profession. The service was at the church of St. Sulpice, which was entirely draped, was very impressive and beautiful.

A most touching incident was the playing by M. Batta (an intimate friend of Dr. Ricord's) on his violoncello, the "Adieux de Marie Stuart," a favorite musical *morçeau* of his deceased friend. Addresses were delivered by Dr. Pean, in behalf of the Academy of Medicine, and M. Peyron, on behalf of the Public Assistance.

Incompatible Drugs.

The *Druggist's Circular*, December, 1889, commenting on the careless prescription of incompatible drugs, says: The latest in this line comes from a correspondent of the London *Lancet* of September 28, 1889. This innocent individual states that he prescribed for a patient suffering from painful rheumatism, antipyrin with salicylate of soda, and was astonished after a few hours to find that the compound had resulted in the formation of a hygroscopic cream. Later he tried to mix antifebrin with salicylate of soda and found that the two previously white powders now formed a pink powder. The writer wants to know what the changes are in these instances; whether new compounds are formed; if so, their formulæ; and whether the pharmacological (sic) action of the drugs is destroyed by such combination. He says, further, that since he discovered the effect of the union of antipyrin with salicylate of soda he has ordered the two drugs in solution. Whether he puts them both in the same solution, or, exhibiting them in separate solutions, allows the patient to test their incompatibility in his stomach, he does not say; but in any case it is a very dangerous tampering with drugs the chemical compatibility of which has not been established.

It is to be hoped that some chemist will put these observations to the test and give the correspondent the desired information. It might be well, also, to suggest to him that this sort of chemical experimentation will some day kill its man by the development of a poison from the union of two non-poisonous compounds.

Bacteriology.

The bacterial origin of malaria was suspected many years ago, even before the invention of the microscope. In a treatise by Marcus Terentius Varro, *De Re Rustica*, written about 114 B. C., the following passage occurs in a chapter giving directions for the building of a house in the country: "Attention must be also paid as to whether there are marshy places, but for the same reasons, and because when they become dry, certain minute animals breed, which the eye cannot discern, and which borne through the air, penetrate into and within the body, by the mouth and nostrils, and propagate obstinate diseases. A situation on which the sun shines all day is more salubrious, for if any animalcules breed and are brought there, they are either blown away or they soon perish from drought." The passage is certainly a remarkable one, although it is impossible that Varro could have possessed any of our modern knowledge on the subject.—*Popular Science News*, December, 1889.

NEWS.

—The deaths of fourteen infants in London last week were attributed to "overlaying."

—Dr. William C. Krauss has been elected lecturer on Pathologie at the Niagara University Medical College.

—The University of Basle is the only one in Switzerland which still refuses to admit women to its medical teaching.

—Dr. Neumann, of Vienna, who attended Dom Luis I, the late King of Portugal, during his last illness, received a fee of about $20,000.

—Dr. Thomas J. King, a prominent physician of the "Southern Tier," died in Machias, Cattaraugus Co., N. Y., on November 5, 1889.

—A reception was given at Rochester, on November 29, to Professor Joseph Leidy, by the resident alumni of the University of Pennsylvania.

—The Municipal Council of Rome has decided to establish a training school for nurses, under the direction of Professor Durante, the well-known surgeon.

—The French Government have appropriated out of legacies left to the State, the sum of 4,000,000 francs for the erection of a French hospital in Constantinople.

—Several cases of food poisoning, one of which has terminated fatally, have recently occurred in the neighborhood of Carlisle, England, due, it is thought, to the eating of pork pies.

—During the first half of the present year, 6,796 persons were vaccinated in the town of Naples and the villages round it. Of these, 6,355 were successful, the result in 3 cases being doubtful, and in 300 *nil.*

—Mr. Henry K. Jessel, assistant to Professor Pitt, in the Department of Natural Sciences, at the Buffalo High School, has been elected Assistant in General Chemistry and Physics in the Medical Department of Niagara University.

—It is officially stated that between July, 1888, and August, 1889, 60,385 persons died of cholera in the Philippine Islands. Both the authorities and the people seem to accept the situation as quite in accordance with the eternal fitness of things.

—Dr. R. S. Huidekoper's resignation from the Veterinary Department of the University of Pennsylvania has been accepted. Mr. Charlemagne Tower, Jr., has been elected Manager of the Veterinary Hospital. Professor C. H. Dolley was added to the Veterinary Faculty as Professor of Biology.

—A syndicate of English capitalists have subscribed £1,000,000 to start and operate a beef extract and meat canning works in the Argentine Republic, and have engaged a Chicago meat packer to act as their agent. The projectors intend to compete with Herr Liebig, the famous beef extract manufacturer.

—A disease has made its appearance in the Springwater Valley, N. Y., that is said to be baffling the skill of the local physicians. The disease, according to the local lay papers, resembles malaria, during its first stage, but when treated for that develops into typhoid fever of a low form and lasting from six to eight weeks, at the end of which time death usually takes place. Up to December 5, forty cases were reported.

—Reports from Illinois, dated December 4, state that diphtheria is very prevalent in various parts of the State. A physician of Macon reports 75 cases, with 5 deaths, while two physicians of Illopolis report 57 cases with 7 deaths. At Macon and other towns the public schools have been closed. At Clinton, Ill., the United States Post Office has been quarantined on account of the spread of the disease. The disease is also prevalent in Monticello, Ill.

—Two prominent surgeons in Pittsburgh are charged with having left a pair of forceps in the abdominal cavity of a woman after a laparotomy. The presence of a foreign body was discovered by another surgeon, whom the patient had called in, and the wound was reopened and the forceps removed by him. The surgeons who made the first operation acknowledged having missed the forceps at the time, but refuse to believe that the instrument was found in the abdomen.

—Professor E. E. Eichwald, of St. Petersburg, died on November 2 of carcinoma of the bladder. Dr. Eichwald was formerly Professor of Medical Diagnosis at the Medico-Chirugical Academy of St. Petersburg; later was promoted to the chair of Clinical Medicine and made Chief Physician to the Military Hospital. It is to Dr. Eichwald that the profession in Russia owes the establishment of the clinical institute for the instruction of qualified men, which bears the name of the Princess Helena Paulovna.

Permanent Pepsin.

THE INSEPARABLE STANDARDS OF VALUE ARE PERMANENCY AND ACTIVITY.

WHEN a physician prescribes pepsin and his patient finds that it "sticks to the paper," that it forms a gummy mass "in powders," he may rely upon it that FAIRCHILD'S PEPSIN has not been dispensed; if he has ordered Fairchild's, this behavior is positive evidence that he and his patient have been the victims of "substitution."

Pepsins which are hygroscopic, which do undergo upon exposure to air the changes characteristic of peptone, are offered (in the form of scales and in powder) with pretensions to permanent quality.

If a product is sought, of well-proven permanency and of highest standard of activity, FAIRCHILD'S PEPSIN is the one which will never give cause for complaint.

Fairchild's was the original "Scale Pepsin;" the first positively "free from starch, sugar, acid, peptones or any added substance." The host of imitations of "Scale Pepsin" bear witness to the value and reputation of the original.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders,** is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds,** handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, **Burn-Brae** offers, for the care and treatment of its inmates, a pleasant, safe, and healthful HOME.

EAR PRESENTATION.—PLEURISY IN CHILDREN.[1]

BY EDWARD P. DAVIS, M. D.,

VISITING OBSTETRICIAN TO THE PHILADELPHIA HOSPITAL, ETC.

Ear Presentation.

Gentlemen: This morning I will tell you of a case which was recently in the Maternity, and will give you a few practical ideas which it will be well for you to bear in mind. The woman was a multipara, and her pelvic measurements were as follows:

Between the spines	27	centimetres
" crests	27½	"
External diagonal	18	"
One of the pelvic diagonals	18	"
The other " "	20	"
Circumference of pelvis	82½	"

[1] Delivered in the Philadelphia Hospital.

The position of the child was diagnosticated as left occipito anterior; the heart sounds were 133 per minute, and the presumptive diagnosis was that the fetus was a male. The labor proceeded normally and the head descended into the pelvis. During an interval of relaxation between the pains, however, the head suddenly swung round, and the right ear of the fetus presented. This is a complication which, if not attended to, may lead to delay in the labor, impaction of the head, possibly to version, and still more rarely to craniotomy. In some cases this may be remedied by placing the patient upon that side towards which the occiput is presenting, elevating the hips and flexing the thighs, when spontaneous rotation may occur, and the head present normally. This failing, obstetrical instruments must be resorted to, one of the best being the antisepticized hand of the obstetrician. Dr. Strengel, the resident, immediately inserted his hand, pushing up the forehead and pulling down the occiput, and the labor proceeded normally to delivery.

Pleurisy in Children.

I will now speak to you upon the subject of pleurisy in children. Owing to the inclemency of the weather I am unable to bring before you the child whose case I present. Pleurisy in children is not rare. This statement was controverted years ago when it was thought that pleurisy was limited to the adult age. Children not only can have pleurisy but do have it about as frequently as adults. The difficulty, however, consists in making a correct diagnosis, and often the condition is overlooked. The disease in children arises from the same causes as those which produces it in adults. Thus, we may have an infectious pleurisy, due to a micrococcus of some sort; then again, it may arise as an inflammation, the result of a caries of a rib, or as a complication of tubercular infection; or it may be associated with pneumonia or bronchopneumonia. It may further follow one of the exanthematous diseases, or occur during the stage of convalescence after rheumatism.

The diagnosis is obscured by the fact that the child will not accurately locate the pain. Most pains are referred by children, either to the head or to the abdomen. Then a physical examination will give us less definite information in children than in adults. Still, percussion is a valuable aid in forming a diagnosis. The child may show an elevation of temperature, 102° or 103°, a rapid pulse, rapid respiration, and cough. If it be an infant it cries when it coughs, and it cries because it coughs. This shows that there is pain of an acute character caused by the movement of the respiratory apparatus. In percussion we may get some slight dulness at the base from the beginning effusion. Auscultation reveals vesicular respiration over both sides, but diminished over the diseased side, and exaggerated over the sound side, and somewhat bronchial in character. At the apices, particularly of the diseased lung, we get bronchial breathing associated with a tympanitic note, sometimes known as Skoda's tympany, and supposed to be due to a consolidation of the lung below. When we examine the child's chest, we are struck with one fact, and that is the presence of the line of empyema of necessity. This is the line an empyema will take if left to develop spontaneously, and this "necessity point" of empyema in children gives us a clue where to look for the first bulging of the chest. It is found more commonly in the anterior portion of the chest at the junction of the second and third ribs with the sternum. The first and second interspaces often bulge early. If we measure the chest from the spinal column to the centre of the sternum on each side we may find but little difference. Occasionally the diseased side will be smaller than the other if the disease be chronic, while, if the disease be acute and the amount of exudation large, it may be enlarged. Respiration may not be at all disturbed. Again, the physical sign in a child's chest in pleurisy changes marvelously from day to day. We may have dulness or percussion with bronchial breathing on one day, while on the next they will be absent. To avoid making any mistake in this matter we should hold the child for some moments in one position before percussing in order to allow the fluid to gravitate to the dependent side. There is nothing characteristic in the cough of pleurisy in children. The effusion may be serous, sero-fibrinous, or purulent. Occasionally caseation, decomposition of the pus and the formation of green matter with the ptomaines will occur. The resolution of a serous exudate is often very rapid. A serous exudate may at times give rise to a high temperature and lead us to suspect pus when it is not present. When a purulent effusion is present it may be marked by a low temperature. In time, however, it will give rise to symptoms of constitutional depression which should not be mistaken for anything else. We should always suspect this condition in cases presenting an irregular temperature followed in a few days by bulging of the chest. The actual test for the nature of the fluid is to be made by means of the hypodermic needle or the fine needle of an aspirator, the operation performed antiseptically. We may puncture the lung several times without doing any damage if the syringe is clean, the skin be well cleansed, and the thrust made quickly and deeply, and the piston of the syringe slowly withdrawn. In old cases the canula may be blocked by fibrinous masses, and no fluid escape. We should always put the fluid obtained under the microscope, and study carefully the characteristics of the bodies seen in the field. If the exudate be serous, all that we shall find will be some blood corpuscles, free epithelial cells and threads of fibrin. If it be purulent, we should notice the character of the pus cells, whether they be old and dead, or healthy and vigor-

ous. On the distinction between these points will often depend the question of the treatment.

It may be well to ask: What will nature do in these cases, if we do nothing? In the serous cases, infants can generally manage the disease themselves, and if they are in good condition, very little treatment is needed. The sero-purulent exudation, however, must have a different method of treatment. If left to nature, the pus will burrow into the mediastinal spaces, the pyogenic membrane will become greater in extent, hectic will occur, and the cavity be emptied by the spontaneous formation of fistulæ. Then, if the pleuritic exudate be complicated with pneumonia or tuberculosis, it will form and reform as new portions of the pleura become affected, it being simply a part of the main process.

A serous exudation needs some treatment in the beginning of the case. When such a condition exists there may be some displacement of the heart, and the child, as an adult, lies upon the diseased side. Thus, if it be a left-sided pleurisy, it will nurse from the right breast of the mother, and mothers will tell you that there must be something the matter with the left breast, because the child will not take it. As a matter of fact, the left pleura is more often affected, in the proportion of four to one. In treating a beginning pleurisy the first indication is to apply cups. If it be a strong, healthy patient, you may use the bleeding cups, but in the majority of cases the simple dry cup, with a rubber bulb attached, may be used with greater comfort, and as efficiently relieve the pain. We may then place the child in a tepid pack, by wringing some flannel out of tepid water, and wrapping it around the child from the suprasternal notch to the umbilicus. This will give relief and exercise a favorable influence upon the course of the disease. Antipyrin in small doses is the best sedative in most cases. As the disease goes on, if the effusion be serous, we may give diuretics, the simpler the better. The best is water in large amounts. The salts of potassium and sodium, especially the citrate of potassium, are of value. A good combination is digitalis, liquor ammonii acetatii, and nitre; this acts both as a febrifuge and diuretic. The child should be kept quiet in a warm bed, and the temperature of the room should be regulated. The bowels should be kept open, and liquid food administered.

If empyema exists, what then shall be done? This is a question which is often disputed, equally good authorities taking opposite views. It is not always necessary to open the chest; but it is necessary to get the pus out. The simplest rule is first to try to empty the chest by aspiration, but not to delay this effort, for the pus may begin to disintegrate, micrococci form in it, and a chronic abscess produced. A simple piston syringe may be used for the purpose of aspiration. This is merely an exaggerated hypodermic syringe with a series of needles of various sizes. If we happen not to have an aspirator, we may apply the principle of the syphon. A trocar and canula may be inserted, the trocar withdrawn and the end of a long rubber tube slipped over the canula. This must be filled with an antiseptic fluid up to the end of the canula. The end of the rubber is allowed to drop into a vessel and then the pus, if fluid, will begin to run out. Aspirators are many and numerous, and work largely on the principle of the piston and valve. In using an apparatus for emptying the chest, certain precautions are necessary. Great gentleness should be practiced, with gradual withdrawal of the fluid. If the chest be emptied rapidly, dyspnœa may be produced with collapse, and more rarely death. Then the injection of antiseptic fluids into the chest has produced death. Before the operation, the patient should have a little stimulus, such as whiskey or brandy and water. A reclining position should be adopted. It is rarely necessary to use an anæsthetic for the purpose of aspiration, and an anæsthetic would mark the symptoms of danger. If sudden pain, dyspnœa, and exaggerated cough occur: stop at once. Give an anodyne to relieve the cough. Upon the removal of the needle close the wound with adhesive plaster.

How often shall we aspirate? Twice and no more, according to the best authorities. After two aspirations, if the fluid reforms, we have reason to fear that the patient's condition will become that of a chronic suppuration. We must then institute permanent and thorough drainage. An incision must be made into the wall of the chest, and a rubber tube introduced into the pleural cavity and allowed to remain, cutting off an inch or two every day. There is a decided disadvantage in this, namely, the presence of the tube, which tends to irritate the part and to produce a permanent fistula between the lung and the pleura. The better operation is to open the

chest freely. This is done preferably in the eighth or ninth interspace in the axillary line, though some go as high as the fifth or sixth. The incision should be made at the upper border of the rib, the tip of the finger introduced and moved freely about to break up the adhesions. Then a small tube should be introduced and held in place by a stitch. If the pus is offensive and decomposed, irrigate the chest with an antiseptic fluid. Then apply an antiseptic dressing, and place the patient upon a stimulating and supporting diet. If resection of the ribs is resorted to, remember the position of the intercostal artery at the lower border of the rib. Cut down upon the centre of the bone, raise the periosteum and do a sub-periosteal operation; and the bone will form again. Resection has frequently been practiced on children. Three-quarters of an inch from one or two ribs may be removed to give sufficient room for drainage. In ordinary cases recovery is prompt. If performed late, when the periosteum of the ribs is diseased and tubercular affection has become grafted on the empyema, the prognosis is almost hopeless.

The case which I had intended to show you is that of a girl between two and three years old. Empyema followed whooping-cough and broncho-pneumonia. Aspiration was performed once, and between three and four ounces of pus was evacuated. Her temperature has not risen since, her general condition is excellent, and we hope that the empyema was circumscribed or loculated, and that recovery will be permanent. We shall incise and drain the pleural cavity thoroughly if further empyema occurs.

REOPENING AN ABDOMINAL WOUND; CHRONIC OVARITIS FOLLOWING SPECIFIC VAGINITIS; UTERINE HEMORRHAGE FROM PROBABLE ABORTION.[1]

BY E. E. MONTGOMERY, M. D.,
PROFESSOR OF GYNECOLOGY IN THE MEDICO-CHIRURGICAL COLLEGE; OBSTETRICIAN TO THE PHILADELPHIA HOSPITAL.

Reopening Abdominal Wound.

Two weeks ago I operated upon a woman forty years old, suffering with a malignant growth of one ovary. As there were very extensive adhesions, which had to be torn up; a drainage-tube was introduced. The patient was very restless after the operation and in her movements the tube was displaced, so that it no longer drained the abdominal cavity, and was removed on the third day. The patient did well, however, until the end of a week, when there was an elevation of temperature, which continued in spite of methods taken to reduce it. Vaginal examination revealed a collection of fluid in the pelvis, and an attempt was made to open through the vagina; but feeling the sac give way internally while the manipulation was being made by the vagina, I made up my mind at once to reopen the wound. A foul collection of serum was found in the immediate vicinity of the ligated pedicle. This was sponged out; the cavity thoroughly irrigated, a drainage-tube introduced and the wound again closed. The drainage-tube was surrounded by rubber dam and the wound subsequently frequently flushed, without the necessity of disturbing the dressing. The wound was reopened on the twelfth day after the operation, the temperature had been high for five days, but now at the end of two weeks the patient is improving as rapidly as could be expected. (This patient subsequently entirely recovered.)

Chronic Ovaritis following Specific Vaginitis.

This woman is a domestic about eighteen years old. Her father and mother were healthy and died from unknown causes. She has had the ordinary diseases of childhood and was never rugged. Menstruation appeared when she was fifteen. A year and a half ago she had an attack of rheumatism for which she was treated in this house. She has suffered from an attack of vaginitis due to exposure to a specific virus. She has never been pregnant. She entered the house last fall complaining of pain in the left ovary, for which the organ was removed, after which all the distressing nervous symptoms of which she had complained, disappeared. Two months ago, the pain returned in the right ovary.

Thorough examination discloses absence of any growth upon the left side, as you would naturally expect from the history of the former laparotomy; but on the right side she is exceedingly sensitive, presenting an indication of either chronic hyperemia of the ovary, or ovaritis. This condition

[1] Delivered at the Philadelphia Hospital.

would explain her distress and neurasthenic appearance. In all cases presenting the subjective symptoms of this patient we would proceed to make a careful examination of the condition of the pelvic organs, and especially of the appendages to the uterus. This examination is made by the conjoined manipulation, introducing one or two fingers into the vagina, as the calibre of that canal will permit. In careful examination it is better to use the finger of the hand corresponding to the ovary to be examined; thus the left hand for the left ovary, and vice versa. The examination is not complete until the rectal touch has been practiced. Let me caution you not to pass the finger from the vagina into the rectum without cleansing, for in cases of vaginitis you are likely to carry the poison and set up a rectitis that may cause your patient great inconvenience. On the other hand the introduction of the finger into the vagina after removal from the rectum, without cleansing, will be likely to offend the sensibility of your patient so much as to lead her to dispense with your services. I have been told of the discharge of a physician for having wiped his fingers upon the patient's mon veneris after a vaginal exploration.

The ovaritis in this patient is, without doubt, due to the specific vaginitis. The ovaritis was attended with severe pain, and was accompanied, partly from the pain, and partly from the reflex influence upon the surrounding organs, with a marked neurasthenia. During menstruation, her pain is very much lessened, because the flow decreases the ovarian congestion. Anemia is a marked symptom, in this case, and is usually so; the ovarian hyperemia leading to free loss of blood during menstruation favors this condition, on the other hand the anemia tends to increase the quantity of the flow.

The treatment is local and general. The former consists in counter-irritants to the region of the ovaries and to the surface of the uterus. Probably the best is the use of electricity: varying its use between the faradic current with a bi-polar electrode and the galvanic current with one electrode in the uterus. The general treatment consists mainly in building up her health by the proper use of tonics, rest, out-door exercise, and pleasant surroundings. The operation of laparotomy should be deferred as long as possible, unless it is evident that the tubes or ovaries contain pus, when every delay is but time lost.

Where the operation is done because of specific infection, it is better to remove the organs upon both sides, and where one organ is left because it seems comparatively healthy, it will soon be found to be the seat of a redevelopment of the disease leading the patient to be subjected to the necessity for another operation.

Uterine Hemorrhage: Probable Sequel of Abortion.

The next patient I show you is a woman with this history: She is thirty-one years old, and has been suffering for several weeks, and, as you see, she is very pale and anemic. Her father died from phthisis, her mother from heart disease. She had the ordinary diseases of childhood; began to menstruate in her thirteenth year, and continued regularly. She has had two children, both of whom were still-born. One month ago she had a chill, and lost she says three quarts of blood. Two weeks ago another chill occurred again with hemorrhage, and one week ago there was a pint of blood lost accompanied with a chill. The uterine cavity was then subjected to curetting. As this operation was done before her entrance we are ignorant of what light it threw upon the condition. No hemorrhage has taken place since.

What is the cause of the hemorrhage in this patient? This is a very important question, for upon its solution depends largely the treatment to which it will be wise to subject her.

Uterine hemorrhage may occur from a variety of conditions. As exuberant granulations upon a lacerated cervix; villous degeneration of the endometrium; uterine polypi or myomata epithelioma of cervix or body; products from incomplete abortion. It may also result from diseased conditions outside of the uterus, as cystic degeneration of the ovaries, or it may arise from systemic affections as chronic diseases of the heart and kidneys; as the result of infection of various poisons, as typhoid, malaria, etc.

She has a lacerated cervix, as there is only slight eversion and no exuberant granulations it is evident that this is not the cause. The uterus is of nearly normal size and in correct position, the ovaries are not found to present tenderness or other characteristics

of disease. Hence we can say that the hemorrhage is not a symptom in this case of polypi. Malignant degeneration of the uterus, myomata within its walls, or cystic diseases of the ovaries. That it is not due to disease of the heart, liver or kidneys is evident from the absence of any other symptoms of disease of those organs. We are led by the process of exclusion to the belief that this condition has arisen from one of two causes: either as a result of malaria, or from an incomplete abortion. Although there is nothing in the history of the patient to confirm the diagnosis of probable pregnancy, I am inclined to believe that the attempted expulsion of the products of conception were the cause of the repeated hemorrhages; could we know the character of the products obtained by curetting, we could probably be certain in our diagnosis. It is true, the hemorrhages were accompanied by chills, but these were irregular, occurring at long intervals, and the patient has shown no disposition to a return since the curetting.

This patient is an instructive one. She impresses upon us the extreme importance of carefully investigating each individual organ. If the physician had attributed to the laceration of the cervix the symptoms and performed the operation upon her the distressing condition of the patient would have become aggravated. Nor should we hastily resort to laparotomy. The proper procedure in hemorrhage from the uterus, where the physical signs afford no interpretation, would be the dilation of the uterus so that the finger may explore its cavity. If granulations are present the curette should be used, fibroids may be enucleated, and astringents applied, where it arises from endometritis. Where the uterus is free from disease, we must direct our treatment according to the knowledge derived from the investigation of other organs.

It should not be forgotten that hemorrhage may arise from the vagina following vaginitis or it may come from a caruncle of the urethra. This enumeration will impress upon you the importance of a general examination and of having a general knowledge of the practice of medicine, before entering upon the practice of a specialty.

—Five children were bitten by a vicious dog while returning from school near Fort Recovery, Ohio, Dec. 16. The newspapers say that all have since developed symptoms of hydrophobia.

COMMUNICATIONS.

SKIN-FLAP OPERATION FOR THE RADICAL CURE OF HERNIA.

BY W. A. HAWLEY, M. D.,

CRESTON, IOWA.

I have originated an operation for the radical cure of hernia, which, in five cases, has proved a success. I say that I have originated the operation, for the reason that I cannot find anything like it in the literature on the subject, and also because I am the only one, so far as I know, who has ever done the operation.

This operation I will call the "skin-flap operation." It is performed as follows: The hernia is reduced, and the parts are first washed with soap-suds and shaved, after which they are washed with an antiseptic solution. A portion of the skin over the external abdominal ring, inguinal canal, and internal ring, in the shape of a parallelogram two inches wide and about four inches long, is then denuded of its epithelial layer with a sharp curette. After the surface of the skin is denuded and the hair follicles and sweat glands are destroyed, leaving the surface raw, I remove a triangular piece of the whole thickness of the skin, above and below the ends of the denuded territory of

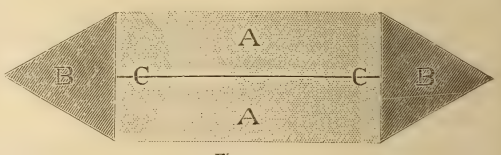

Fig. 1.

skin as represented in the diagram (Fig. 1). Two skin flaps are now made by carrying an incision longitudinally through the denuded skin, parallel to the sides and midway between them, from above downwards, directly over the internal ring, the inguinal canal and the external ring. The skin is next dissected up on both sides far enough to allow the skin to be drawn forward until the sides of each triangle meet.

Then a section is made through the external oblique, the internal oblique, and the transversalis muscles to the peritoneum, thus destroying the external ring, the canal, and the internal ring. The wound is then closed and the operation is completed by drawing the skin flaps forward and passing them down into the incision through the deeper

structures and under the muscles, and suturing them. The suturing is done with silver wire. Each piece of wire is armed at each end with a needle, and the needles are passed from within outwards, one on each side, going through the inverted denuded skin, the muscles, and the skin on the surface. Each suture is left incomplete until all the needles have been introduced and drawn through to the eye. Then, beginning with the upper suture and proceeding regularly downward, both needles of each suture are drawn through the tissues at the same time, and the wire is fastened. A drainage-tube may be placed in the lower angle of the wound, and the whole is dressed as in any other operation. In every case so far healing by first intention has occurred, leaving a solid retracted cicatrix; and to all appearances it is

Fig. 2.

impossible for hernia ever to occur on the operated side.

I return to the abdominal cavity all tissue that is returnable and leave the sac in situ to increase the strength of the cicatrix, cutting through the sac and leaving as much of the sac tissue on one side as on the other, bound in, or hemmed in, by the skin flap. If I find it necessary to remove the sac or part of the omentum, I do so.

The distinctive feature of this operation consists in the method adopted to completely obliterate the external ring, the inguinal canal and the internal ring.

I have now operated upon five patients in this way and have had them under observation, after the operation, for from nine months to two years. To perform the denuding of the skin has been the most tedious part of the operation for me, as I have no battery, therefore I have used a sharp curette. A galvano-cautery would, perhaps, be the best thing to use.

It is interesting to note what becomes of the spermatic cord during and after the operation. In Gray's Anatomy it is stated that "in the male the spermatic artery and vas deference may be divided" in operations for hernia; and this is just what I do. Practically, I pay no particular attention to the cord, but cut right through the canal lengthwise, taking care not to injure the nerves. Ordinarily, I use only one set of sutures, namely, that which unites the line of the inverted skin surfaces, making the stitches on each side go through the skin which is turned under, as well as that which covers the abdomen on each side of the opening. In two of the operations I used a set of superficial sutures, placed in the intervals between the deep ones. In the three other cases only straps of adhesive plaster were needed to make the coaptation accurate; and union by first intention resulted in all five cases.

I have so far employed this operation only in cases in which an operation was necessitated by strangulation; but it may be capable of a wider application. I would not advise any operation where there is little danger of strangulation; but, if a hernia has been strangulated and successfully reduced, and is liable to strangulation at any time, I would not hesitate to operate; or, if a patient should insist upon an operation, after he had been informed of *all the dangers*, I would proceed to operate, and would expect a favorable result, with our present knowledge of antiseptic measures.

ANEURISM OF THE AORTA SIMULATING CARDIAC VALVULAR DISEASE.

BY GEORGE DOCK, M. D.,

PROFESSOR OF PATHOLOGY, ETC., IN THE TEXAS MEDICAL SCHOOL AND HOSPITAL.

Aneurism in the beginning of the aorta, although rare, presents as a rule such a peculiar train of symptoms, that the narration even of isolated cases is not without value. In the present case, a slight variation from the usual site affected has given rise to a group of symptoms closely resembling those of a much more common class of diseases. While engaged with a ward class one day, I was so attracted by the appearance of a man just admitted as to make him the subject of immediate study before the class. The patient supported himself in an arm-chair; his countenance and attitude expressed intense drowsiness and exhaustion. His skin was cyanotic, the cervical veins dilated and pulsating, and his respirations frequent and shallow. His hands and face were puffy, and unbuttoned shoes revealed the thick ankles. The whole appearance, in short, indicated advanced cardiac insufficiency. The history then obtained was as follows:

M. N., 45 years old, barkeeper, born in

France. There is no history or evidence of syphilitic infection. He denies alcoholic excesses. The patient gives a history of unimpaired health up to four months before admission, when he began to cough, to feel short of breath, and to lose in weight. Soon after, his ankles began to swell. He was treated for phthisis, but later his physician told him his heart was affected, and prescribed digitalis. Growing worse in every way he came to St. Mary's Infirmary in Galveston.

The patient is of medium size, heavily built, and moderately emaciated. The skin is flabby, cyanotic, and slightly icteric, as are also the visible mucous membranes. Extreme anasarca exists, less marked in upper limbs and head. The thorax is well formed. The apex beat of the heart in sixth intercostal space in nipple line is exaggerated. There is a visible thrill all over the cardiac area, which is limited entirely to the diastole. The cardiac dulness begins above the fourth rib; extends to right edge of sternum and to nipple line. On auscultation a double murmur is heard. The first, synchronous with the apex beat, is loud, harsh, and rasping. It is heard equally well over apex, base, and aortic cartilage, and is also audible in the axilla and in the back. It is apparently the same murmur heard in the places named. Following this immediately, is another murmur, blowing, long and moderately loud, best heard above apex, but audible all over the heart area. It is synchronous with the thrill. The second sound at the aortic cartilage is present, though masked by the murmur. The pulmonary second sound is not markedly accentuated. The systolic murmur can be heard in the neck, though faintly. The radial pulse is 105, and quick, but of good tension. On the right side the pulmonary resonance ends in dulness in the fourth interspace in the nipple line, movable according to position; on the left in the seventh intercostal space in the axilla. Respiration shallow, accompanied by numerous loose râles, especially on the right side. The liver dulness extends two inches beyond the costal margin. The abdomen is somewhat distended, but no fluid can be detected in it. The tongue is flabby and thinly coated; there is loss of appetite, constipation, and a dull frontal headache; also scanty expectoration of frothy mucus. For several days shortness of breath has been so severe that patient could not lie down. The urine is scanty, and high-colored, specific gravity 1.030, and contains a small amount of albumin, no casts.

The result of this examination was not as satisfactory as I had expected. Though the suspicion of valvular disease seemed confirmed, the physical characteristics differed from usual in some particulars. The frequency of the heart beat made it difficult to time the murmurs and thrill, though they seemed to be as given above. The pulse seemed unusually strong, considering the evidences of insufficiency, but its character was attributed to digitalis. The suspicion of aortic disease was abandoned, and notwithstanding certain misgivings, the case was demonstrated repeatedly as one of double mitral disease, and was seen casually by various physicians without leading to any important change of opinion. Digitalis was pressed at first with great benefit. The œdema and cyanosis lessened, the dyspnœa was so slight that the patient could sleep lying down. The thrill became less marked; the murmurs continuing as before. Very soon, however, the drug seemed to have lost its effect. The dyspnœa again became so severe that aspiration was resorted to, and about a pint of sero-sanguinolent fluid removed from the right pleural cavity. This was of but little benefit, and, with increasing weakness of the circulation, death ensued. At the autopsy an unexpected condition was found. The autopsy notes bearing on the symptoms are as follows:

" . . . The right pleural cavity contains about twenty ounces of bloody serum and flakes of fibrin. The right lung is compressed, the lower and middle lobes collapsed, and non-crepitant. Their pleura is covered with a thin fibrinous coat; the tissue tough and bloodless at the periphery, but the area around the root infiltrated with blood. In the left pleural cavity there was a small amount of bloody serum, the lung slightly compressed, but crepitant throughout and œdematous. The bronchial mucous membrane is injected and covered with frothy mucus. The pericardium is adherent to the pleura on the left side, and closely adherent to the heart. The heart enlarged and both ventricles dilated. The left ventricle measures 12 cm. in length, its wall 18 mm. at 1 cm. below the ring. The aortic valves are slightly thickened but not retracted; aside from this the valves and endocardium are normal. The muscle shows no gross lesion. All the cavities contain mixed clots. The opened aorta measures 8

cm. at the insertions of the valves. The sinuses are not dilated. Beginning just above the valves is a diffuse dilatation, extending around two-thirds of the circumference of the aorta with the convexity of the vessel as its middle. It is from two to four centimeters wide and bounded above by a thick band which gives the aorta a constricted appearance, though the lumen is not diminished. The surface of the aorta in this part is covered with atheromatous scars and calcareous plates and shows the orifices of two saccular aneurisms. The first is just above the sinus of the right aortic cusp. Its shape and size are such that it fits the thumb for a distance of two centimeters. It projects to the right of the pulmonary artery, touching the upper part of the right ventricle. It is empty, and its walls are smooth and thin. The second is further to the left, in the concavity of the aorta, just above the common insertion of the posterior and left leaflets of the aortic valve and the left coronary artery. Its orifice measures four by three cm.; the lateral edges are sharp and rigid, the upper border is formed by part of the firm band mentioned above. In the widest part the sac measures six cm.; its depth is five cm. Its wrinkled walls are covered by a thin, white, fibrinous layer, and are marked by a longitudinal ridge in the posterior part, corresponding to the auricular septum. The relations of this aneurism were studied by filling it loosely with wool, opening the auricles and examining the several cavities. On the right side it encroaches on the auricle and the superior vena cava, so that the capacity of the auricle is lessened about one-third and the lumen of the vein reduced to a narrow slit. On the left, the anterior wall of the auricle is bulged back, forming a rounded prominence directly over the mitral valve and causing an actual obstruction. The branches of the pulmonary veins from the lower and middle lobes of the right lung cross over the tumor and are almost occluded by the displacement so caused." . . . The other organs, especially liver and kidneys, showed the changes common to obstructive disease in the heart. The kidneys in addition showed beginning arterial sclerosis.

The lesions found explain the clinical phenomena so clearly that comment is hardly necessary. In an incomplete search of the literature of aneurisms in the beginning of the aorta I have not been able to find reference to one in the concavity. Their usual seat is in the interior wall, or still more rarely above the posterior leaflet, with symptoms of obstruction of the pulmonary artery or superior vena cava. The difference of half an inch to the left is enough to produce the mitral symptoms and the obstruction to the pulmonary circulation, and indirectly the systemic symptoms. The larger aneurism was so placed as to allow considerable expansion without rupture into a neighboring cavity or vessel, for notwithstanding its size, the walls are strong. Although the absolute rarity of such a lesion may bring the conclusion that it is of little practical value, yet it conveys an important lesson in the value of minute examination even when the condition seems plain, and furnishes a remarkably good example of the simulation of disease.

THE ANATOMICAL RELATIONS OF LESIONS OF THE HEART AND THE KIDNEYS IN BRIGHT'S DISEASE.[1]

From the Study of Three Hundred Autopsies.

BY HENRY F. FORMAD, B. M., M. D.,

DEMONSTRATOR OF PATHOLOGY AND MORBID ANATOMY, AND LECTURER ON EXPERIMENTAL PATHOLOGY, UNIVERSITY OF PENNSYLVANIA.

In the present paper I give an account of my studies from three hundred autopsy records of Bright's disease.

I will limit myself chiefly to the consideration of hypertrophy and fatty metamorphosis of the heart as occurring in this disease. There are a number of other points of interest that may be gleaned from these records, but upon which I will not dwell now beyond stating general results. Some of the points gained from the analysis of my tables give results which are at variance with those obtained from the collective studies of cases of Bright's disease made by some authorities. The reason for this may be looked for, however, in the classification of the material, the direction of study, or the purpose for which any given class of cases had been collected, or sometimes selected. My studies are purely morphological, being made at the autopsy table and in the laboratory upon consecutive cases of Bright's disease as they occurred during a

[1] Read before the Association of American Physicians, 1889.

given space of time. They are unbiased; not being a clinician, I have no theories or hypotheses to follow out, and refrain from making any suggestions regarding the mechanism of the production of cardiac and renal changes, and for the present I will not go into the details of the etiological relations of these affections.

Of the three hundred autopsies upon cases of typical Bright's disease, one hundred and fifty were studied by myself *post-mortem*, and most of these also microscopically; in fact, the specimens from every case where the naked-eye appearance was not conclusive, were thus examined. The source of these one hundred and fifty autopsies is from the coroner's material of the city of Philadelphia, through the courtesy of Coroner S. H. Ashbridge, for whom, in conjunction with Dr. R. R. Stewart, I conduct all the autopsies of cases of sudden deaths or those unattended by physicians. Another source is furnished by private autopsies, which I frequently make at the request of physicians. All these cases occurred in a total of eleven hundred and seventy-two consecutive autopsies of adults, and were executed between September 1, 1888, and September 1, 1889. It will be seen from the tabulated results given below, that in general these cases are not unlike the hospital cases, which are not included in this series.

The other one hundred and fifty autopsies were taken from the *post-mortem* records of the Philadelphia Hospital (the large almshouse hospital of this city). I abstracted them with the aid of my assistant in this work, J. F. Spelman. They were all made on subjects of typical Bright's disease, mostly diagnosticated as such or studied during life, being selected from a total of thirteen hundred autopsies from the hospital records stated, covering a period of five years. Many of them had been executed under my supervision and that of Dr. E. O. Shakespeare, while in the rest the cases were clinically studied and the autopsies executed by the members of the hospital staff, which included Drs. Tyson, Bruen, Osler, Musser, Wilson, Henry, Curtin, and Walker. These hospital records, although not sufficiently detailed regarding the weight of the heart and kidneys, are accurate, and will serve our purpose.

Each series of cases is separate and distinct, no cases being duplicated; and each case is recorded separately and in detail in the second part of this paper.

In the preparation or collection of these records, Bright's disease was taken as the starting-point or basis. All cases of kidney affection other than Bright's disease, or those in which the disease did not present itself as fully established at the autopsy, and a few ill-recorded cases, were excluded. In the hospital and private cases the clinical diagnosis was paid attention to: an advantage which was not enjoyed in the coroner's cases; yet, even in the latter, sometimes the most truthful of histories were obtained under oath upon the witness stand, especially regarding habits of the deceased.

In the series of my own autopsies, which were made with the special purpose of presenting the results in these studies, the weights of the heart and of the kidney were taken carefully in nearly every instance, as stated in the records; likewise the condition of the *body* was noted, while its weight was approximately estimated. I believe this was in most cases an almost true estimate, being correct within the limits of a few pounds. Naturally the ability to do this requires practice.

The estimation of the weight of the body is all important as regards the question of the normal size of either heart or kidneys; because, while a heart weighing twelve ounces may be called hypertrophied in an individual of one hundred and twenty pounds bodily weight, it may be considered of normal weight in an individual weighing two hundred pounds. My figures of the approximate weight of the body are satisfactory for this purpose, because a mistake within a few pounds (of bodily weight) could be no definite mathematical factor; moreover, there are other more serious obstacles to the precision in calculating proportions, such as the condition of nutrition of the body and the contents of the alimentary canal.

In statistics relating to the weight of the heart found in the literature of Bright's disease these points, these facts—the importance of which is readily seen—have not been taken into consideration by any one, as far as I know. The same is true of the relation of the weight of the kidneys to the bodily weight in Bright's disease.

From the given weight of an organ a satisfactory estimate of its size can be made. I found the weight of organs to be a much safer criterion and more satisfactory than measurements, the latter being made by the different observers according to various

scales, methods, and ideas, which are often quite unintelligible and useless. The heart muscle especially varies in thickness according to the degree of contraction, the quantity of clotted blood, and the time which has elapsed since death. The plain statement of an experienced observer as to the condition of the cavities, the walls, and the approximate weight of the heart is more valuable than all the measurements that an inexperienced and over-zealous one will present with his figures.

From the present considerations I exclude amyloid disease of the kidney; in which there is a marked and nearly constant apparent absence of hypertrophy of the heart, although this belongs to the picture of Bright's disease. This is true as far as the small size or weight of the heart is concerned at time of death; but if it be considered that we usually meet with amyloid disease in scrofulous subjects, who invariably have congenitally small hearts, the conclusion that hypertrophy of the heart is rare in this affection will be found to be an error.

The small heart of the scrofulous is subject to hypertrophy as well as the heart of the normal individual; but when the former hypertrophies to double its original size, it may not appear any larger in volume than the latter, and when, in reality, enormously hypertrophied it may barely reach the size of what we ordinarily would call a slight hypertrophy. I made some studies upon the weight of the organs, in relation to the size of the body, in the scrofulous, according to the methods of Beneke and Thoma for establishing such weights, and paid especial attention to hypertrophy in amyloid disease. I shall present these observations on another occasion.

Cases of congenitally small kidneys and of senile atrophy were carefully excluded in Series A, these autopsies having all been executed or the organs personally studied by myself. I also excluded from the present records cyanotic induration of the kidneys, which, as is well known, is usually the consequence of cardiac disease, especially valvular. I may state here that my researches have fully convinced me that cyanotic induration of the kidney never terminates in Bright's disease, which is quite contrary to the opinion of some observers. I have reference to the long-standing passive hyperemia of the kidneys which results in cyanotic induration of these organs, with enlargement often to double their normal size, the kidneys being hard and firm and bluish-red in color.

The alcoholic cyanosis of the kidney, another affection analogous morphologically to the last named, but different only in the shape of the organs (the "pig-backed" kidney, which I first described and demonstrated before this Association, as reported in Vol. I of its *Transactions*), I also excluded. Alcoholic cyanosis is often associated with cardiac hypertrophy, but rarely with valvular disease. It is this affection which is often mistaken on the *post-mortem* table for, and recorded as acute Bright's disease. I doubt not that this lesion (the alcoholic kidney) represents the inflammatory form of Bright's disease of Grainger Stewart, which he records as being without albuminuria, without dropsy, and with large fatty livers, and which has crept now and then into the records of various observers, old and recent, as cases of acute Bright's disease. I also believe some of the subdivisions of the "pluralists" on Bright's disease, such as the "chronic hemorrhagic nephritis without dropsy of Weigert," to be identical with my alcholic cyanosis.

The late stage of the alcoholic cyanosis (the œdematous form), as met with upon the *post-mortem* table, in chronic drunkards who had been deprived for some time of alcoholic beverages, resembling much the large white kidney macroscopically, is another source of error. This lesion I have seldom seen to give rise to left-sided hypertrophy, though general hypertrophy is common.[1] Amyloid kidney also closely resembles and is often mistaken for the large white and the fatty and contracted kidney.

Such mistakes and the omission (to be referred to later) of some authors to separate the fatty and secondarily contracted kidney from the primarily contracted or granular kidney, cripple the statistics on the subject of hypertrophy of the heart quite decidedly.

In recording my cases I have adopted the rather crude and old-fashioned nomenclature for the various forms of Bright's disease, but one which I am sure will be readily comprehended; whereas did I use the proper technical terms, misunderstanding on

[1] It is remarkable how infrequent Bright's disease is in drunkards. I found that inflammatory kidney lesions generally occurred more frequently in the temperate than in the intemperate. Is it the constant excess of venous blood in alcoholic cyanosis of the kidneys that makes inflammatory changes less frequent, as it does in the right chambers of the heart?

the part of the reader as to exact form of Bright's disease meant, would be sometimes liable to occur.[1]

The classification adopted is as follows:

I. Acute parenchymatous nephritis (*Syn.:* catarrhal, tubular, desquamative, croupous, scarlatinal, febrile or glomerulo-nephritis, acute degeneration of the kidney, acute exudative nephritis, acute diffuse nephritis) I will term *acute Bright's disease.*

II. The early stage of the chronic parenchymatous nephritis (*Syn.:* same as above, qualified by "chronic") I will invariably refer to by the term, *large white kidney*, which well indicates the stage of the disease.

III. The late, or contracting stage of chronic parenchymatous nephritis (*Syn.:* diffuse nephritis, secondarily contracted kidney, obstructive nephritis, fatty kidney, chronic diffuse nephritis with exudation) I will designate by the term, *fatty and contracted kidney.*

IV. Chronic interstitial nephritis or primary contracted kidney (*Syn.:* granular, cirrhotic, or gouty kidney, renal cirrhosis, atrophic lithemic or toxemic nephritis, chronic diffuse nephritis without exudation, etc.) I will speak of as *red granular kidney;* which is an old and comprehensive name for this affection.

Among the most serious sins of nomenclature we find that the term diffuse nephritis is indifferently applied to both the fatty and contracted and the red granular kidney. The reasons for a separation of these two affections as distinct forms of Bright's disease are quite obvious; and I put myself strongly on the side of those who make it, viz., the dualists.[2]

For diagnostic purposes and for prognosis it is also quite essential that the *fatty or secondarily contracted kidney* should be differentiated from the *red granulur or primarily contracted kidney.* Clinically it is, I believe, well established, that in the former the onset of the disease may nearly always be traced to acute nephritis, or at least to the large white kidney; that it is liable to occur at all ages; that transitions from scarlatinal nephritis in the young are traced to the large white kidney of the adult, and to the fatty and contracted kidney of late life, while rarely to the very old; that dropsy is very common in the earlier stages; that polyuria is more rare, and albumin is seldom missed; in fact, the duration of the disease is very uncertain, a fatal termination being liable to occur at any time.

On the other hand, in the *red granular kidney*, which is common in gouty and rheumatic individuals, and is so often traced to disease of the genito-urinary tract, the initial stage is unknown, there being nothing to show that an acute inflammation of the kidney ever existed. It rarely occurs in the young,[1] being almost peculiar to middle or old age; it may be of lifelong duration; dropsy and presence of albumin are rare, and polyuria is prominent.

Polyuria in the fatty and contracted kidney, if it occurs at all, is late; the urine may be rich in albumin; whereas, in the ever-present copious flow in the red granular form, little or no albumin is present, as is well known. This I believe to be an important diagnostic point.

In my laboratory classes the urine examined is often from well-known clinical cases, and in many instances have I traced the albuminous (fatty and contracted kidney) and non-albuminous polyuria (red granular kidney) to the *post-mortem* table.

I may be permitted to introduce the following table relating to the more important anatomical and microscopical differences between the two affections referred to, because their separation is to a certain extent a point of issue in hypertrophy of the heart, and

[1] I am not considering here the histology of Bright's disease, hence it is unnecessary to review the anatomical and histological features of the various forms of this affection; but a statement of the array of synonyms may prevent misunderstanding.

[2] It is interesting to observe that Bright, Grainger Stewart, Dickinson, Johnson, and the English school are strictly "dualists," being reinforced by the great original German workers, Virchow, Traube, Senator, and Bartels; by Charcot and Cornil in France; and, in this country, perhaps most strongly by Tyson. The French are mostly "unicists" (*i. e.*, advocates of the eventual transition of the three parenchymatous forms of nephritis into the red granular kidney), in accordance with the views of such prominent Germans as Frerichs, Rosenstein, Cohnheim, and Bamberger, and, it appears, also with the views of some of the New York authorities on the subject. Of late years "pluralists" have arisen, chiefly among the Germans, including Wagner, Weigert, and even Senator, who are inclined to ascribe every form of Bright's disease to different and independent morbid processes and causes, and who place several complications of the morbus Brightii in the field as independent subdivisions of the disease.

[1] Eight cases in persons under 30 years of age will be found in my record. Histories of syphilis, malaria, and anemia in these cases.

ANALYSIS OF 300 CASES OF BRIGHT'S DISEASE (EXCLUSIVE OF AMYLOID DISEASE).

fatty metamorphosis of the cardiac muscle.[1]

Difference between Fatty and Contracted and Red Granular Kidney:

Contraction of kidney secondary.	Contraction of kidney primary.
Size seldom below normal.	Size below normal, often reduced to one-half, or even one-fourth.
Capsule adherent only in places, seldom thickened. Surface lobulated, often smooth. Color pale, mottled or yellow.	Capsule adherent, thickened. Surface granular, rough. Color red or grayish-red.
Cysts usually large, and seldom numerous. Pelvis rarely dilated.	Cysts usually small-sized and numerous. Pelvis often dilated.
Arterial changes rare, or not pronounced.	Arterial changes (endarteritis, or periarteritis) almost invariably present.
Cortex often normal in size; atrophy very late.	Cortex always much atrophied.
Renal epithelium much swollen, desquamating freely, often in a state of fatty degeneration, but cells always visible. Compound granule cells present.	Renal epithelium never desquamating, though it may undergo fatty degeneration (necrosis), and become diminished in size and partly lost.
Tube casts epithelial, dark granular, and containing compound granule cells, and later fat globules.	Tube casts hyaline, pale granular, and waxy, but never containing epithelial cells, or any other.

Analysis of the Cases.

The three hundred autopsies from which I draw my conclusions (two series: A. coroner's and private cases, B. hospital cases) are, as stated, recorded in detail in the second part of this paper, which will be published in the volume of Transactions of this Association. I think it well to record them there, as future studies of the same by any one may reveal points of interest at present unconsidered. Each case has a reference either to my note-book, to the autopsy records of the Philadelphia Hospital, or to those of the Coroner, so that, should additional information be desired, it may be gained therefrom.

The large general table given below contains a summary of all the cases referred to in this paper, and gives the duration of life, the cause of death, the condition of the body, dropsy, cystic change of the kidney, and the prominent cardiac complications, such as hypertrophy, valvular disease, fatty metamorphosis, and dilatation of the heart, as well as the arterial changes in each form of Bright's disease, stating the number of cases. The figures expressing the percentage, side by side with the number of cases, facilitate comparison with other statistics.

Beside this I have compiled several special tables which give interesting data relating to hypertrophy of the heart under varying conditions, fatty metamorphosis of the cardiac walls, valvular disease and pericarditis, and the weight of the heart and kidneys in each of these affections.

I also present tables relating to age and sex, and further some interesting figures concerning the weight of the heart in relation to the weight of the body, and finally some data relating to the distribution of Bright's disease during the various periods of life.

References will be found in the records to arterial changes, and a summary of the various complications or concurrent affections of Bright's disease.

Conclusions.

From the above general table the following conclusions may be drawn:

Hypertrophy of the Heart.[1]

Hypertrophy of the heart in Bright's disease generally, occurred in all the cases tabulated in 62 per cent., of which 34 per cent. were left-sided and 28 per cent. were general hypertrophy. Hypertrophy was absent in only 38 per cent. of all cases.

[to be concluded.]

[1] If the classification and the definition of Bright's disease in its various forms were undisputed and a uniform nomenclature adhered to by all, then there would be no discrepancy in statistical results such as is seen in the literature of the subject. I would earnestly urge the adoption of a uniform nomenclature for the various forms of Bright's disease, and the abolition of some of the synonyms. Some of the latter are misleading, and I have met with instances where pathologists and clinical teachers would designate one and the same form of Bright's disease by entirely different names (without thinking that they were identical) and also, under a certain given name, affections entirely different from one another. Others delight in suggesting and using new names for the various forms, without giving synonyms when writing on the subject, and leaving the reader to conjecture from the description which form of the affection they really mean.

[1] To secure the figures regarding cardiac hypertrophy, each of the two series of cases is first considered separately, viz., by adding the total number of cases of parenchymatous and interstitial nephritis together and dividing by 150; the two results then being added and divided by two. For instance: General cardiac hypertrophy, *Coroner's and private cases:* In parenchymatous forms of nephritis, 22 cases; in interstitial nephritis, 13 cases; a total of 35 cases, which equals 23 per cent. *Hospital cases:* Parenchymatous forms of nephritis, 28 cases; interstitial nephritis, 22 cases; a total of 50 cases, which equals 33 per cent. By adding the two results (23 per cent. and 33 per cent.), and again dividing by two, 28 per cent. is obtained, which equals the percentage of general hypertrophy in the *total of cases.*

CREMATION.

WHAT IS THOUGHT OF IT BY PHYSICIANS.

INTERVIEWS WITH PHYSICIANS BY A REPRESENTATIVE OF THE MEDICAL AND SURGICAL REPORTER.

FIRST SERIES.

DR. WM. HUNT, on being visited, said that personally he has not much sentiment in regard to the disposal of the body after death, and had no choice between becoming an articulated skeleton, or being burned or buried. If anything, the former, as a condition of usefulness, would be most pleasant to him. Hygienically speaking, Dr. Hunt is of the firm opinion that cremation is the only right and proper method for the disposal of the dead. Of this he thinks there can be no doubt. The popular prejudice against cremation, he says, is most absurd. Whether the body is buried or burned, it is cremation all the same; the only difference being that in the one method the combustion is very slow, and in the other very rapid. Ultimately the body becomes dust, and it is merely a question of, perhaps, twenty odd years, or a few brief hours. Regarding the cremation of his family, he would be apt to follow their requests as to the disposal of their bodies, but would not for a moment hesitate to cremate them should they desire it. Dr. Hunt does not believe in graveyards, in visiting and mourning over the graves of our dead, or in covering them with flowers. He prefers to think of the dead as they have been when alive, and not associate their memory with the horror of death. He most heartily advocates the introduction of cremation into this country.

DR. WM. GOODELL is of the opinion that cremation should be obligatory and in the hands of the State authorities, and not in charge of speculators. He thinks it is the only right and lawful way to dispose of the dead. Dr. Goodell favors cremation for three principal reasons: the first being hygienic, the second sanitary, and the third æsthetic. It is his sincere wish that his body shall be cremated—to insure it against any possibility of desecration, if for no other reason. In these days, when towns and cities are growing so rapidly, who knows but what our remains may be dug up, in a few years hence, to make room for some church or other building. He would like to make provision for the incineration of his own remains. Dr. Goodell firmly believes that the ground is polluted by bodies buried in it, and to him the question of cremation is of vital importance. It should be in the hands of the State, under the direction of the Boards of Health, and it should be vigorously enforced. The main objection raised to cremation, viz., that it would render impossible the tracing of any poisons, is of but slight weight in contrast to the great hygienic value of the method.

DR. ROBERT P. HARRIS said he would rather be buried than cremated and thought he would also like his relatives to be interred in the old-fashioned way. There is still plenty of room for burial near cities, and he did not think it would cause much crowding. Regarding the value of cremation, he had never given it any thought, and would not like to give an opinion, other than that he considers it an unnecessary precaution.

DR. GEORGE STRAWBRIDGE said that, from a sanitary point of view, there is no question as to the superiority of cremation over burials. Of this, he claimed, there can be no doubt. It is unquestionably the only fit and hygienic method for the disposal of the dead. Sentimentally speaking, he confessed that he does not altogether favor the method. He had seen one crematory and was not pleasantly impressed with it. He did not like the idea of being baked in an oven, and it would be painful for him to think of this being done to the body of any of his family. On the other hand it is hard, also, to bury a loved one in the ground. The question viewed in this light is merely one of æsthetic taste. Dr. Strawbridge does not think that cremation will ever become popular in this country; the German element favors it, but not the American. He thinks that burials, if properly conducted, might be made to comply entirely with all principles of hygiene, but at present these laws are continually violated. Burials in damp or wet ground are certainly dangerous, and he understands that water is said to be often seen in the bottom of the open graves in a Roman Catholic cemetery of this city, which is situated on very low ground, and that the coffins are sometimes lowered into an inch or so of water.

DR. W. S. W. RUSCHENBERGER most heartily favors cremation, from both a hygienic and sentimental point of view. Regarding

the disposition of his own remains he is most philosophic, and, if the preference were given him, would prefer being sent, as an unknown body, to some school of medicine, there to be dissected. He claims that the remains of our families are of no possible use to us, and their keeping or preservation can do us no possible good. We cannot resole them like an old shoe. However, these bodies might, very possibly, do great harm. Cremation is the only means of obviating this possible, and even probable, evil. Dr. Ruschenberger then related the story of a sea-faring friend who had desired him to choose a burial place for him. The Doctor asked if he had any choice; to which his friend replied, "Not so long as it is on a hillside, for I have a dreadful fear of having my body waterlogged."

Dr. Charles Hermon Thomas favors cremation in a mild degree, both from a hygienic and sentimental point of view. Dr. Thomas said it was rather obnoxious to him to contemplate the fact that with their Schuylkill water Philadelphians are imbibing a vast amount of filtrations from their deceased friends in Laurel Hill; although, on the whole, it seems to agree with them fairly well. The cremations of Dr. Gross and others had impressed him most favorably. Personally he would as soon be cremated as otherwise, and would feel the same way regarding his family. It would be hard to thrust a loved one, although dead, into a glowing furnace; but it would be equally hard, if not harder, to lay that body in the cold, damp ground. Dr. Thomas does not think the ill effects of inhumation very serious; still serious results are possible and cremation would do away with these. While he would never start a crusade for cremation, he must say that he approves of it. Still, the *pros* for cremation are not sufficient to warrant its being made obligatory or a State matter; neither are the objections to burial sufficient to warrant its universal introduction.

Dr. Henry Hartshorne was seen at his Germantown residence and was found to be very favorably impressed with cremation. He heartily favors the entire destruction of the dead body. Its preservation, such as embalming or mummifying, is most distasteful to him. For it to be speedily reduced to its natural elements is pleasant and proper, both æsthetically and sentimentally. Our present methods of disposing the dead are far from what they should be. The open grave, the lowering of the casket, the weeping relatives, the rattle of the earth upon the coffin, are all most revolting. If incineration does away with the painful and unnecessary adjuncts of death it is sentimentally as well as hygienically far superior to inhumation.

Dr. T. H. Andrews said that, although when Demonstrator of Anatomy at the Jefferson Medical College he both advocated and practiced the cremation of the remains of all anatomical specimens, and had utilized the ashes in various ways, still, personally speaking, his sentiments are averse to cremation. To him it appeared akin to annihilation. After the body of a friend has been laid in the earth, there still seems something left with us; but if the body is burned, all seems lost. To him the cremation of the body of Dr. S. D. Gross was most painful; it is horrible to think that within four-and-twenty hours after the death of the great surgeon there was nothing left of him but a handful of ashes. Dr. Andrews never wants to be cremated, neither would he ever allow any of his family to be incinerated. He does not think the practice will ever become popular in this country.

Dr. Andrews then introduced our representative to

Dr. G. Milton Bradfield, who, after recovering from the misapprehension that the representative of the Reporter was the agent of a crematory, expounded the opinion that as long as the Latin races predominate in this country, cremation will will never be universal; but that when the Saxon element supervenes, the introduction will only be a matter of time.

Periscope.

Poisoning by Illuminating Gas.

In an article in the *Cincinnati Lancet-Clinic*, Dec. 7, 1889, Dr. J. C. Crossland, of Zanesville, Ohio, says it is the consensus of opinion among chemists and experimenters that carbon monoxide and the hydrocarbons are the poisonous constituents in illuminating gas. Analyses show that water gas contains from three to four times more of these factors than coal gas, and is therefore more dangerous. Our knowledge of the action of these poisons on the economy is incomplete. We know that carbon monoxide breaks up the oxyhemoglobin of the blood, forming with the hemoglobin a stable union,

thereby deoxidizing the blood. Some authorities claim that the effects of illuminating gas on the system are not due alone to the deoxidation of the blood, but that it has a narcotic action on the central nervous system.

He then describes a case under his care. The patient was a strong young woman who stopped at a hotel. She was assigned a room and immediately retired. At 5 A. M., the clerk went to her room to call her. On approaching her room he found the hall full of the odor of gas. On forcing the door the woman was found nearly dead, and the gas turned on.

Attempts at resuscitation were made by Drs. Draper and Brush, with stimulants, pure air, and the Faradic current; but little was accomplished until Dr. Crossland was called and administered hypodermic injections of a ten per cent. solution nitroglycerine. Fifteen minims of the nitroglycerine solution were injected into the epigastrium. The good effects of this on the heart action were perceived in about five minutes, though it soon became evident that several hours would elapse before the system could throw off the poison sufficiently for the patient to regain consciousness.

The treatment by hypodermic injections, chiefly of nitroglycerine, was continued at intervals varying from thirty minutes to two hours, according to the indications, and was supplemented with the use of the Faradic current.

Antiseptic Properties of Corrosive Sublimate in Minimal Quantities.

The powerful antiseptic properties of corrosive sublimate have only recently been fully appreciated, and experience has shown that equally positive results are obtainable with attenuated solutions as with dangerously strong ones.

Dr. François Scalji has recently been experimenting with very weak solutions of the sublimate and has found that when used at a temperature of 115° to 125° F., solutions of a strength of 1:10,000, 1:20,000, and even 1:50,000, and 1:100,000, are capable of exerting germicidal actions equal to those of solutions of 1:1000 or 1:5000 at a lower temperature.

Dr. Scalji's experiments, which are reported in the *Bulletin Médicale* October 2, 1889, were, briefly stated, as follows: First, he filled ten test tubes with fresh, normal urine. The first two of these were not treated; to the second pair a small quantity of a 1:1000 sublimate solution was added; to the third pair of tubes a similar quantity of a 1:5000 solution; to the fourth pair a 1:10,000, and to the last two, the same quantity of a 1:20,000 solution. Then one tube of each pair was kept at a temperature of from 59° to 77° F., and the others at a temperature from 115° to 125° F.

It was found that the two tubes to which no sublimate had been added soon began to undergo fermentation. The second pair, treated with the 1:1000 solution, remained completely sterile. With the third and fourth pair similar results were obtained. Finally, the last two tubes were examined, and it was found that in the tube kept at a normal temperature fermentation had been retarded for a few days, whilst the tube kept at a temperature of 115° to 125° remained sterile after the lapse of a month. The experiment was frequently repeated and always yielded the same results.

Similar experiments were then made with meat juice and milk, and the results were identical with those obtained with urine.

Finally, the bacillus of erysipelas on cultures of gelatine and blood serum were treated with weak solutions of sublimate, and it was observed that if the cultures were kept at a temperature of 150° or 125° sterilization was permanent and complete even when solutions of 1:50,000 or 1:100,000 had been employed; whereas if the cultures were kept at a normal temperature, solutions of the above strength merely retarded their development for a few days.

The clinical value of these experiments is very evident, for, if satisfactory antiseptic results are obtainable with a 1:100,000 solution of corrosive sublimate, neither surgeon nor obstetrician need be circumspect regarding its free use. The irritant or caustic action of the stronger solutions will be absent, and the danger of poisoning through absorption entirely removed.

Ammonia in Cocaine Poisoning.

A case of poisoning by a very moderate quantity of cocaine is reported by Dr. Golovkoff, in the Proceedings of the Caucasian Medical Society, where ammonia was used with good effect to restore the patient. The patient was a somewhat delicate woman, who was suffering severely from toothache.

The pain becoming unbearable, Dr. Golovkoff injected fifteen minims of a two per cent. solution of the hydrochlorate of cocaine under the skin of the left cheek, which gave relief for three or four hours, when the pain returned as acutely as ever. A second fifteen minims were injected, and in about five minutes' time the patient became restless, her pupils dilated, the surface of the skin became pale, the pulse and likewise the respiration became rapid, and shivering came on; the respiration soon ran up to 200 per minute, and was labored. A curious effect, too, was produced on the sounds of the heart, causing them to be audible at the distance of two paces from the patient. There was great pain over the cardiac region and back, together with a dread of death and convulsive movements of the limbs. There was some liquor ammoniæ at hand, and this the patient was given to smell and a few drops were given internally every five or ten minutes. Amyl nitrite was also employed, but the latter seemed to do more harm than good, while the ammonia soon brought the pulse and respiration, and indeed the general condition of the patient, into something more like their natural condition, so that in about a couple of hours she had quite recovered. Dr. Golovkoff remarks that the only case he has been able to find in medical literature where ammonia was used as an antidote in cocaine poisoning was one by Dr. Gooding, of Barbadoes, reported in *The Lancet* of 1888, vol. i, p. 394, and copied into the *Meditsinskoë Obozrênie*. (This was a case of a negress who had developed alarming symptoms after less than half a grain had been injected into the gum; she was treated by hypodermic injections of ether and ammonia.)—*Lancet*, Nov. 30, 1889.

Salpingostomy.

Dr. Skutsch has practiced a new gynecological operation. Since the introduction and general diffusion of salpingotomy as an operation recognized and justifiable, at least in prudently selected cases, many have suggested that at least an attempt might be made to save the diseased tube after opening its occluded cavity and freeing it from adhesions. Practice has shown that the danger of meddling with the affected parts in such a manner, and then closing the abdominal wound, is fraught with risk. Dr. Skutsch proceeds in a systematic manner to conservative ends, or, at least, did so in one case. The patient was sterile and 28 years old. She suffered from pelvic pains, and it is stated Dr. Skutsch diagnosticated obstruction and dilatation of both tubes. This diagnosis was confirmed by abdominal section. A hypodermic syringe was employed in order to puncture each tube and ascertain its contents. As clear yellow serum was drawn away the operator determined to save the tubes. An oval piece, about one square centimetre in size, was cut out of the outer end of each tube, and the mucous and serous coats united by fine silk sutures around the border of the hole thus formed. A sound was then easily passed from the tube into the uterine cavity on both sides. The patient made a good recovery, and was relieved of her pains, but a long after-history is not given. Dr. Skutsch calls this proceeding "salpingostomy." In some cases of pyosalpinx it would be advisable, he thinks, to sew the ends of the tubes to the abdominal wound, to open them and allow them to discharge pus externally. When the discharge ceased to be purulent the tubes might be freed from their artificial attachments and replaced in the pelvis. Dr. Skutsch's paper was read before the congress of the German Gynecological Society in June.—*British Medical Journal*, Nov. 30, 1889.

Misleading Stethoscopic Sounds.

In the *Med. Press and Circular*, Nov. 27, 1889, Mr. G. E. Greene, Medical Officer, of Wexford, says:

The following sources of error in diagnosis when using the stethoscope seem not to be sufficiently dwelt upon, if they are mentioned at all by clinical teachers. Both pupil and teacher frequently spend long periods in practically studying crepitation, etc., and seldom take into consideration that an artistic haired student occasionally generates those sounds in the vicinity of his own ear, whilst a hairy patient having nothing wrong with his lungs produces morbid sounds much better.

Pleuritic friction sounds are well simulated by the patient rhythmically applying his finger ends to his abdominal or other cuticle, while the physician is engaged in auscultation. Taking into consideration the numerous causes of, and necessities for scratching among the lower sections of society and the variability of timbre, rhythm, and intensity

produced according to the locality undergoing massage, the vigor, regularity or irregularity of its application, etc., it need not be wondered at that itchiness may be classed as one of the most frequent causes of phantom morbid stethoscopic sounds. Another source of error is the coming in contact with stethoscope of articles worn by patients, the friction of articles of clothing against each other, sounds produced by the bed when knelt upon, sounds caused by constrained position of the doctor's clothing, etc., in awkward positions whilst examining patients too feeble to be moved, noises arising in the room or next door, the imperceptible slipping of the stethoscope, and last, though by no means least important, bruits in auscultator's ears, the result of catarrh or organic disease.

A suitably constructed stethoscope of the binaural type would in most instances very materially diminish the chances of error in diagnosis, provided, of course, the user was well grounded in the sources of pseudo-morbid sounds.

A Defect in the U. S. Pharmacopœia.

In the *Pharmaceutical Era*, Dec., 1889, Mr. Paul L. Stangl, of Philadelphia, says: The United States Pharmacopœia is open to more than one objection, but none is so flagrant as the one to which I wish to call attention. I received a prescription, and finding the dose rather excessive, it being a very poisonous substance, I sent the prescription back to the physician to have it corrected or verified. The doctor being absent, I sent word for him to stop at the store on his route and was rewarded by his appearance shortly after. After stating the matter to him, it occurred to me to see just what the exact maximum dose is, and, as a pharmacist, naturally turned to the United States Pharmacopœia for information. Imagine my surprise on finding that the book, prepared especially to be the standard and guide by which the druggist is to conduct his establishment, lacked that most essential table, the maximal doses. As nearly every Pharmacopœia in the world has these tables, it was the more surprising to find them absent in the Pharmacopœia of this progressive country. This is of greater importance than it looks at first sight. If, for instance, a physician prescribes a poisonous dose, and the prescription comes into the hands of an ignorant and careless apothecary, he can compound it, and in case of poisoning can go free on two points which the law must allow. First, he can claim having followed the prescription and be irresponsible on that account; or, if he be questioned, if he did not know that the dose was poisonous, he can claim irresponsibility, because the U. S. P., the only book according to which he is compelled to make his preparations, does nowhere state the dose of this or any other remedy. On the other hand, the physician can go free on the same grounds, since his text-books vary the dose exceedingly. In fact, in six or eight different text-books on materia medica and therapeutics, used by professionals, which I examined, I found a range, for example, of tincture of aconite of from 5-8 to 20-25 drops as the highest safe single dose that can be given. In consequence a physician ought to depend either on the U. S. P. or his druggist, who in turn must rely on the U. S. P.

Recovery after Wounds and Operations.

Professor Nussbaum has found that a very good prognosis of the healing of surgical wounds can be obtained by examining the secretion from the surface during the first two or three days. If this be sanguinolent, prognosis is more or less bad. Care must be taken not to confound any slight after-bleeding with true sanguinolent secretion. The prognosis is only bad where the secretion from the whole surface of the wound is tinged with blood. Thus, when a day after a litholapaxy has been performed the urine is quite free from a reddish tinge the prognosis is good, or if two or three days after the amputation of a breast when the dressing is changed there is no general sanguinolent stain on the latter, but only, may be, a few little blood clots here and there, it is most likely that the wound will heal satisfactorily. Again, if the secretion becomes free from blood on the fourth or fifth day, the prognosis, though not quite so satisfactory as if there had been none at all after a few hours, it is still decidedly better than if it continues bloody up till the sixth or eighth day. In such a case the patient is sure, if he recovers at all, to be very slow about it. In phthisical persons and hard drinkers there is nearly always a great

tendency to a prolonged secretion of sanguinolent matter after wounds, and sometimes the tinge remains thoughout the healing process, which is in these cases very tedious. When the secretion on the first day is free from blood, it shows that the capillaries are closed, and therefore that the intracapillary pressure is normal. Again, it is evident that when the intracapillary pressure is low the endosmose and the exosmose between the vessels and the tissues cannot be taking place properly, and thus that the due healing of the wound cannot be expected to proceed as it ought.—*Lancet*, Nov. 30, 1889.

Value of Vaccination.

One of the most striking indications of the value of vaccination which has ever been given by a layman, is that which reached this country in the "Stanley Letters" of Nov. 25. Stanley writes: "The small-pox broke out among the Mayena and their followers, and the mortality was terrible. Our Zanzibaris escaped this pest, however, *owing to the vaccination they had undergone* on board the Madura."

Double Uterus and Vagina.

In the *Virginia Med. Monthly*, December, 1889, Dr. B. H. Brodnax, of Brodnax, Va., reports a case of double uterus and vagina coming under his observation. The subject was a negro woman, 40 years old, whom he delivered of the smallest child he ever saw, at full term. It measured eight inches long, was well-formed and alive, and died half an hour later. While removing the placenta, his finger caught in a loop in the posterior part of the vagina. Several days afterwards he examined the parts, finding a double vagina. Further examination, with sound, disclosed a second womb; the posterior one joined to the anterior, but with a perfect os and cervix, and depth of womb one and one-half inches. The woman had told Dr. Brodnax previously that she had menstruated regularly every month, whether pregnant or not, which caused her not to know when she conceived, or when her full time had come. This he had doubted.

The anterior uterus and vagina were of usual size but the second womb was only about two-thirds the size of the one that had been impregnated, and its vagina was not over a fourth of an inch in calibre. The two vaginæ were distinct throughout—they moving on one another when rubbed between the fingers. The examination was as critical and careful as could be made on a living subject. The woman had evidently never been impregnated in the posterior womb. She is still living, and the birth at which the discovery was made was the sixth.

Sea-water for Gonorrhœa.

In the *Brittsh Medical Journal*, Nov. 30, 1889, Mr. R. F. O'Brien, of Dover, says that during the past two months he has treated thirty-two cases of gonorrhœa by means of sea-water injections, the result being an average duration of disease under treatment of 8.87 days. Each case was kept under observation for about a week after the disease had quite disappeared, in order to ascertain if any return of the discharge occurred. Relapse occurred in one case only.

As to complications, one mild attack of cystitis occurred in a patient who had had a history of cystitis previous to his present attack of gonorrhœa.

The treatment was by sea-water injections, undiluted, seven or eight times during the twenty-four hours, each injection being retained for a few minutes. Latterly warm sea-water injections have been used.

The general treatment consisted in rest, dieting, saline aperients, avoidance of stimulants.

The results have been so satisfactory, as compared with those obtained by other methods of treatment, as to lead Mr. O'Brien to publish them, with a view to eliciting more extended trial. Should further experience confirm the above results, this would prove a method of treatment peculiarly suited to the naval and military services.

The advantages of the method are, that sea water combines an alkaline and antiseptic, with a tonic action on the mucous membrane. It is cheap and universal; for where sea water is not available "sea salt" would probably give nearly as good results. It also suggests itself for the treatment of other mucous membranes such as that of the vagina in vaginal leucorrhœa, etc. The addition of an astringent would probably give even better results, but nothing was used in the above cases other than sea water.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

CREMATION AS VIEWED BY THE MEDICAL PROFESSION.

The subject of the mode of disposing of the human body after death is one of great importance to all men; but it is one in which medical men have a peculiar interest. To others it may be a matter of sentiment or of prejudice; but the medical man, from his familiarity with the processes of dissolution and his incessant regard for the influence of every controllable process upon the health of the community, must look upon it with special concern, and at the same time with special fitness for expressing an intelligent opinion in regard to it.

It is well known that the desirability of adopting cremation as a method of reducing the human body, after death, to its original gaseous and mineral elements has appeared clear to many physicians, and that from time to time desultory and occasional expressions of this opinion have appeared in medical and even in lay journals. But now the REPORTER presents, for the first time, we believe, to its readers the opinions of a considerable number of well-known physicians on this important subject. These opinions have been secured by direct application, in interviews by a member of its editorial staff, and are given as faithfully as possible.

The physicians who have met our proposition with courtesy deserve the thanks of their fellow-physicians, and we have no doubt their views will have great weight with the community. As will be seen from the interviews published in this number of the REPORTER—which are but a part of those already secured—the profession cannot be said to be unanimous; but there seems to be a strong preponderance in favor of cremation. This is largely founded—as might be expected—upon hygienic considerations. When the series begun in this number is completed, it is hoped that we shall have a full representation of the medical men of the country. We have not been able to publish in this issue the opinions of all the eminent physicians of this city whose views will be looked for with interest; but they will appear later. The interviewing will be followed up in other cities, and when the work is complete it is hoped that the sense of the medical profession in the United States will be fairly ascertained, and that this will furnish ground for some distinct opinion, which may guide the community in determining what practical steps—if any—are needed to make the the customs of the people of this country conform to the teachings of good sense as well as of good taste in the matter under consideration.

PHYSICIANS AND POLITICIANS.

The readers of the REPORTER will remember that about seven months ago the smooth current of medical affairs in the Philadelphia

Hospital was disturbed by an attempt by the Mayor of this city to force upon the Staff a physician of his personal choice, who had not received the endorsement of the Medical Board to which the nomination of candidates was delegated under the Civil Service Rules provided for such cases. At that time Dr. James W. White, President of the Board of Charities and Correction, refused to be the tool of the Mayor, and was summarily dismissed from office by him; and the REPORTER, on May 11, expressed editorially its opinion of this high-handed step.

It was then anticipated that the Mayor would follow up his attempt to wreak vengeance on Dr. James W. White by securing such modifications of the Civil Service Rules as would enable him before long to get rid of some members of the Visiting Staff of the Philadelphia Hospital who were obnoxious to him; and it is now reported that he intends to use the opportunity furnished by the annual election—at which it has been customary to re-elect the whole Staff, unless any of them declined a re-election—so as to have a new man chosen instead of Dr. J. William White, the son of Dr. James W. White.

It is to be hoped that this report is erroneous, and that no one of the present Staff will fail of re-election, unless he does not desire it, or there is clear proof of unfitness brought against him. If, however, it is attempted to displace Dr. J. William White, or any other competent and faithful member of the Staff, we believe no physician or surgeon who respects himself, or who has a true sense of professional honor will lend himself to this scheme by consenting to take a place made vacant so unjustly.

The occasion is one which may prove a critical one in the history of the profession in this city, and may be of far-reaching influence outside of it. It is an issue between physicians and politicians, and any physician who at this juncture mistakes its importance and lends himself to be the instrument of vindicating political or personal animosity, or who fails to stand by the fair interests of the profession as a class will deserve the severest censure.

We sincerely hope that the medical men of Philadelphia will be found united on this occasion; and that they will act so as to add to the reputation of the profession in this city and to strengthen the hands of their fellows elsewhere who may be so unfortunate as to find themselves in a similar trying situation.

THE HEART IN PREGNANCY.

The changes produced in the heart by the pregnant state are of great interest; and they have been studied especially by French and German writers. During his term as interne to the Paris Maternité, in 1826 and 1827, J. F. Larcher was struck by the frequency with which hypertrophy of the left ventricle was observed in women, from eighteen to thirty-five years of age, who had died for the most part of puerperal fever. He examined one hundred and thirty such women, and found that the increase in thickness of the ventricle amounted to a third or a fourth above normal. The right ventricle and the auricles were believed by Larcher to preserve their normal thickness. The investigations of Larcher excited great interest. Ducrest subsequently examined the hearts of one hundred women, from twenty to thirty years of age, who had died in confinement, and he was able to confirm the results obtained by his countryman. Following up the history of this question, we find that Larcher, in 1857, presented a memoir to the French Academy, in which he maintained that there was a normal hypertrophy of the heart during pregnancy. According to the excellent custom of the Academy, a committee was appointed to inquire into the statements made by Larcher. Investigations were undertaken at the instance of the committee by Ducrest, Zamboco, Béraud, and Blot, and they confirmed as completely as possible the results already given. Blot, for example, emptied the

hearts of blood and then had them weighed, thus showing that the hearts of pregnant and recently delivered women were heavier than the physiological average in women.

The results given above have not passed unquestioned. Gerhardt examined the area of præcordial dulness in four pregnant women, and upon the insufficient data furnished by these examinations, denied the occurrence of hypertrophy of the heart in pregnancy. He attributes the increase of præcordial dulness found in two of the four cases referred to, to an exaggerated upward curving of the diaphragm, as the result of which the heart is applied more closely to the thoracic wall. Friedreich takes the same view. The researches of Duroziez, however, would appear to establish beyond question the general correctness of Larcher's observations. Duroziez examined the præcordial area of one hundred and thirty-five women, either delivered or about to be delivered, and found the superficial dimensions of the heart to approach those of a man. He found also that the greater the number of pregnancies the greater the tendency of the heart to remain large. Ordinarily the heart diminishes to nearly the normal size within ten days after confinement, becoming smaller in those who do not suckle their infants; while suckling keeps up the hypertrophy of the heart.

It is evident that in examining the hearts of women to determine the changes which take place in a normal pregnancy, those cases should be eliminated in which the women have died of puerperal fever, or have had nephritis, because these diseases can themselves produce hypertrophy of the heart. When these precautions have been taken, the results obtained by different careful observers seem to indicate that hypertrophy of the left ventricle in pregnant women is not constant, and that it is frequently associated with dilatation. According to Fritsch, hypertrophy is not found, but only dilatation, which affects the least resistant parts of the heart—the right heart and especially the auricle. Löhlein takes substantially the same view. Macdonald believes that hypertrophy of the heart really exists, but that its frequency has been exaggerated; he admits that it is accompanied with a certain degree of dilatation of the different cavities of the heart.

It will be seen from what has been said that the earlier French writers were almost unanimous in maintaining that hypertrophy of the heart is a constant accompaniment of pregnancy; and that the German writers, on the other hand, were disposed either to ignore the occurrence of heart changes altogether, apart from puerperal fever and nephritis, or to attribute them to dilatation. The truth lies somewhere between these extreme views; in fact, the later French writers, such as Du Castel, Letulle, and Porak, have approximated somewhat to the views expressed by the German writers cited.

When one considers that in pregnancy the total volume of the blood is increased, and that it is at the same time diminished in nutritive power, it becomes evident that increased demands must be made upon the heart under circumstances calculated to weaken it. If, however, the woman starts with a good heart, and keeps up her nutrition throughout pregnancy, one can understand how hypertrophy may predominate over dilatation. In all probability the heart in most cases of normal pregnancy undergoes in a slight degree both hypertrophy and dilatation, the former affecting chiefly the left ventricle, and the latter the auricles and the right ventricle.

CORRECTION.

In the Clinical Lecture by Dr. Louis Starr, in the REPORTER, Dec. 7, 1889, page 623, 7th line from end of page, "50 per cent." should read "5 per cent." This is the strength of oleate of mercury ointment recommended by Dr. Starr for use in hydrocephalus.

—The influenza epidemic is spreading in Central and Southern Germany. A large number of cases are reported in Munich, Mayence, Cassel and Leipsic.

Book Reviews.

[Any book reviewed in these columns may be obtained upon receipt of price, from the office of the Reporter.]

TREATISE ON SURGERY. By T. Holmes, M. A., Cantab., Consulting Surgeon to St. George's Hospital, etc. With 428 illustrations. 5th Edition. Edited by T. Pickering Pick, Surgeon to St. George's Hospital, etc. Large 8vo, pp. 1008. Philadelphia: Lea Brothers & Co., 1889. Price: cloth, $6; sheep, $7.

The most striking feature of this edition of Dr. Holmes's book is that we can discover in it no evidence of such revision as the date on the title-page would lead one to expect, or as would be creditable in 1889 to the authorship of Mr. Holmes or the editing of Mr. Pickering Pick. This defect is the more conspicuous and the more astonishing when we consider that no corner of the world is ignorant of the enormous changes which have taken place in regard to the theory and practice of surgery within the last five or ten years. The book before us contains a fair account of the antiseptic method of Lister, but in the body of the work there are statements which were true only before antiseptic surgery was fully developed. Thus, on page 57, we read that contused and lacerated wounds "always unite by second intention"—which is elsewhere described as involving pus-formation. Elsewhere we read "The union of compound fractures is by granulation," and that immediate union of the wound can generally be secured only "if the wound is a mere puncture." "If the wound is larger or the edges are lacerated or contused," he adds, "it will be useless to attempt to close it."

One of the most striking examples of the utter failure to revise this edition is to be found on page 116, where, in speaking of the treatment of hydrophobia, Pasteur is said to have reported his experiments "within the past few months," and his method is described as the inoculation of virus from a dog into a monkey and back again from the monkey into a dog! Again, Dr. Rouge's operation on the nose, published in 1873, is referred to (page 661) as "lately introduced."

In other portions of the book, where the question of abdominal section comes in, the opinions given are those of twenty years ago rather than of to-day! The old idea that opium is "indicated in all forms of traumatic peritonitis" has been abandoned by many of the most successful operators of the world; and for a general treatise, published in this year of grace, to advise the reader to "place reliance" only upon "opium, stimulants and fomentations," in cases of purulent peritonitis, is indeed remarkable; especially when no mention is made of abdominal section, with flushing and drainage, in the face of the favorable results which abound in literature.

No clear description of any one method for the radical cure of hernia is given in the work. In the author's opinion all operations, even the most recently devised, usually fail in their object unless assisted by a truss. In vaginal hysterectomy, tying off the broad ligaments by ligatures is alone advised; a method which, on account of its high mortality from hemorrhage, has been almost wholly displaced, the world over, by the clamp forceps, allowed to remain.

These are only examples—of which many more could be cited, if our space permitted—of the contrast between the teachings of this edition of Mr. Holmes's book and the present position of the science and art of surgery; and we find it difficult to understand how men of so much reputation as Mr. Holmes and Mr. Pick should appear to be responsible for such a seeming exhibit of ignorance or audacity.

AN EXPERIMENTAL STUDY IN THE DOMAIN OF HYPNOTISM. By Dr. R. von Krafft-Ebing, Professor of Psychiatry and Nervous Diseases in the Royal University of Graz, Austria. Translated from the German by Charles G. Chaddock, M. D., Assistant Physician, Northern Michigan Asylum. 8vo, pp. viii, 129. New York and London: G. P. Putnam's Sons, 1889.

The present volume contains the history of a young woman who was extraordinarily suitable for the study of hypnotism. Her family history was extremely bad: the father was a drinker, and had died by suicide; the mother was sickly, and died paralyzed as the result of apoplexy; the mother's father shot himself while insane; a brother and sister of the patient died by suicide, and a sister was subject to *hysteria convulsiva*. The patient herself had a morbid impulse to suicide, which she abhorred; she also had attacks of hystero-epilepsy, and one attack of catalepsy. When sixteen or seventeen, while on a visit home from the convent where she was studying, she fell passionately in love, and surrendered herself sexually to her lover. She was then sent back to the convent, but escaped. Her subsequent history, up to the time when she came under Prof. Krafft's care, in October, 1887, is one of strange adventure. She committed thefts, sometimes apparently knowingly and sometimes while in a condition of self-induced hypnosis (autohypnosis), after coming out of which she would have no knowledge of her acts. Part of the time she wandered about disguised in male attire. Dr. Jendrássik, of Budapest, experimented with her in March, 1887; from him she escaped, and fled to Graz.

Professor Krafft's experiments with this pathological curiosity were very elaborate and covered a considerable period of time. The subject was absolutely under his control while hypnotized, falling in with all his suggestions and obeying no one else. She even attempted criminal acts at his suggestion. What is more remarkable is the demonstration that the patient could be made to perform acts, after awaking, under the impulse of suggestions made during the persistence of hypnosis. The curious influence of mind over matter was illustrated in the fact that the suggestion that the skin had been branded was followed by an inflammation which left the designated scar behind.

Professor Krafft's experiments are an interesting study in morbid psychology, and have a direct bearing upon certain medico-legal questions. Apart from this we do not see that anything new has been developed. The author believes that two facts have been established: (1) "that the phenomena of hypnotism are of a psycho-suggestive nature; (2) that post-hypnotic suggestion leads to the establishment of auto-hypnosis."

Dr. Chaddock, the translator, has done his work well, and the publishers have presented the book in a handsome form.

Literary Notes.

The *Writer* (Boston) for December is filled with original contributions of interest and value to all who are engaged in literary work. Following a personal

sketch of Mrs. George Archibald are articles entitled "Duplicating Manuscripts," "The Opening Sentence," "'Don'ts' for Young Writers," "Needless Words." A new department, of great practical value, is entitled "The Use and Misuse of Words;" in it every-day questions of language are discussed briefly in a plain and common-sense way.

NOTES AND COMMENTS.

Italian Sausages.

The excitement caused throughout Italy by the detection of extensive frauds in the Bologna sausage manufacture is spreading. Other cities, notably Florence, are demanding an immediate inspection of the same articles of food as are vended in Italian warehouses. The public, says the *Nazione* of that city, are entitled to some such inquiry in their behalf as has just yielded such startling results in Bologna. Instead of the pig's flesh popularly supposed to form the main ingredient in the Italian sausage, horseflesh is that which is really used — horseflesh, moreover, of more than dubious origin, taken from animals that have died of infectious disease, and even that in an advanced state of decomposition. According to the *Tribuna* there has been collusion between certain sausage manufacturing firms and the veterinary authority, the latter winking at frauds which it ought to have exposed. The new powers conferred by the Codice Sanitario, indeed, are finding material for their exercise in quarters hitherto above suspicion —in an industry, to wit, which has long been one of the special boasts of Italy.—*Lancet*, November 16, 1889.

The Radical Cure of Hernia.

At the meeting of the Johns Hopkins Hospital Medical Society, held in Baltimore, October 22, 1889, Dr. Wm. S. Halsted presented five patients upon whom he had performed his operation for the cure of inguinal hernia. He described the operation as follows:

1. The incision begins at the external abdominal ring, and ends one inch or less (less than one inch in children) to the inner side of the anterior superior spine of the ilium on an imaginary line connecting the anterior superior spines of the ilia. Throughout the entire length of the incision everything superficial to the peritoneum is cut through.

2. The vas deferens, with its vessels, is carefully isolated up to the outer termination of the incision, and held aside.

3. The sack is opened and dissected from the tissues which envelop it.

4. The abdominal cavity is closed by quilted sutures passed through the peritoneum at a level higher by 1½–2 inches, than that of the so-called neck of the sack.

5. The vas deferens and its vessels are transplanted to the upper outer angle of the wound.

6. Interrupted, strong silk sutures, passed so as to include everything between the skin and the peritoneum, are used to close the deeper portion of the wound, which is sewed from the crest of the pubes to the upper outer angle of the incision. The cord now lies superficial to these sutures, and emerges through the abdominal muscles about one inch to the inner side of the anterior superior spine of the ilium.

7. The skin is united over the cord by interrupted stitches of very fine silk. These stitches do not perforate the skin, and when tied they become buried. They are taken from the under side of the skin, and made to include only its deep layers—the layers which are not occupied by sabaceous follicles.

Dr. Halsted has for more than two years sewed most of his wounds in this way. The method was suggested to him from his experiments on dogs. He thinks that it is very difficult, and perhaps impossible, to disinfect the skin of a dog, and believes that pyogenic organisms may occasionally be present in the sebaceous follicles of the skin. At any rate, he had repeatedly observed pus in the suture holes of the perforating skin stitches, and could not with any certainty secure primary union of the skin wounds of dogs until he had resorted to this subcutaneous method of sewing the skin. Dr. Halsted remarked in this connection that whether or not it were possible or easy to disinfect absolutely the human skin, he had been much impressed with the fact that skin sutures not infrequently suppurate, even in wounds sewed by the most careful surgeons in this country and abroad. He thought it advisable, therefore, to test for a time the subcutaneous, buried, skin suture.

8. One or two small, short gauze plugs are used as wound drains.

The gauze plugs are removed at the first subsequent dressing—usually at about the

seventh day. The patients are allowed to walk about on the 21st day.—*Johns Hopkins Hospital Bulletin*, December, 1889.

Ainhum, a Brazilian Disease.

Ainhum was first systematically described by a Brazilian surgeon as attacking colored races in Brazil. The merit of its actual discovery, as Dr. Radcliffe Crocker and others have pointed out, is due to Dr. Clarke, who described the disease before the Epidemiological Society in 1860, as a dry gangrene of the little toe among the natives of the Gold Coast. Dr. Da Silva, of Lima, however, described ainhum as a disorder long known as existing amongst Africans and Creoles in South America. Ainhum consists in hypertrophy and degenerative changes in the little toe, a constriction forming and slowly becoming deeper until the digit is amputated spontaneously or otherwise. The disease is often symmetrical and may last for years. It is now known that the fourth, or even the great toe, may be affected, and Egles describes a case where a finger was attacked. It is frequent near Bahia, and also occurs in the Southern States of America, the West Indies, the West Coast of Africa, India (where Hindoos are also liable to the disease), Réunion, and Nossi-bé. The pathology of ainhum is obscure, and although spontaneous amputation of digits is a feature in some forms of leprosy, it is by no means certain that the two diseases are closely allied.—*British Med. Journal*, Nov. 13, 1889.

Chloroform and Locomotor Ataxy.

Dr. Thiem, having had to give a patient with slight signs of locomotor ataxy, chloroform for the purpose of examining an abdominal tumor, was surprised to notice that as she was being helped from the room, while still somewhat under the influence of the chloroform, she walked with a typical ataxic gait, though this symptom was not ordinarily present. On watching other patients who were not suffering from this affection trying to walk while still partially under the influence of chloroform, Dr. Thiem convinced himself that the peculiar gait only occurred in the subjects of ataxia in whom the semi-narcotic state brings out the want of coördination in the movements of the legs. The explanation would appear to be that inasmuch as the peculiar gait is not due to any paralysis of the muscles, but only to the want of coördinating power, which is set in action by the control exerted by the muscular sense and the sense of sight, when, as in the case of a half-chloroformed subject of locomotor ataxy, both the central coördinating apparatus and the peripheral regulating machinery are in a more or less inactive condition, there is a double reason for the existence of the well-known jerking and sliding movements of these patients. It would appear, then, that in doubtful cases of locomotor ataxy some assistance towards a correct diagnosis might sometimes be obtained by partially anæsthetizing the patient and then observing his gait as he walks across the room.—*Lancet*, Nov. 16, 1889.

A New Method of Anti-Rabic Inoculation.

Inspired by the belief of M. Pasteur that the desiccation of spinal cords obtained from animals having died of rabies diminishes the quantity and not the virulence of the rabic poison, M. Hœgyes, of Buda-Pesth, was led to try the effect of simple dilution, and he has successfully carried out seventy vaccinations on this plan without the production of any untoward symptom. He soaks one part of diseased cord in a sterilized solution of sea salt (7 grammes to the litre), the proportion varying from 1 in 10 to 1 in 10,000. The latter dilution does not cause death in the rabbit, but double that strength (1-5,000) will do so, though not invariably. The stronger solutions kill, and each rise in strength corresponds with a shortening of the period of incubation. The author hopes by careful dosage of the virus to obviate the uncertainty which results from using spinal cords of varying dimensions, the process of desiccation upon which the attenuation of the virus depends not being the same in a thick as in a thin cord. Whatever the value may be of these discoveries, they furnish an additional proof that M. Pasteur's method is based on a sure basis of observed facts. By vaccinating animals before infection immunity is, in most instances, conferred against any—even the most powerful—mode of infection. Vaccination *after* infection only protects apparently against the usual mode of transmission, viz., by bites.—*Medical Press and Circular*, Nov. 20, 1889.

Coryza.

The following solution for nasal catarrh is recommended by Professor Leffert, who claims it to be most efficacious:

℞ Acidi carbolici . . . . . ℈j
Sodii boratis . . . . . ʒj
Sodii bicarbonatis . . . . . ʒj
Glycerini . . . . . fʒj
Aquæ rosæ . . . . . fʒj
Aquæ, q. s. ad . . . . . Oj
M. Sig.: Use as a spray.

Anasarca and Ascites in an Infant.

Dr. James Wright Putnam, of Buffalo, N. Y., reports in the *Buffalo Med. and Surg. Journal*, Dec., 1889, the following case:

A boy, eleven months old, with acute general dropsy. The scalp, hands, arms, legs, and ankles all pitted on pressure. The abdomen was greatly distended with fluid. There was no history of previous ill-health. The bowels moved naturally every day. There was no suppression of urine. There had been no cutaneous trouble. Small powders of jalap and cream of tartar were prescribed. These operated freely, and reduced the edema of the extremities to a marked extent.

The ascites, however, was undiminished, and we accordingly decided to tap. We drew off one pint of fluid, which was straw-colored, and did not differ from the usual ascitic fluid. The child made a complete recovery.

Carbolic Acid in the Treatment of Neuralgia.

Dr. Julius Garst, of the Indian Reservation, Tacoma, Washington Territory, writes to the *New York Medical Journal*, November 30, 1889, that recently a case of severe neuralgia, that had continued about three months, came under his care. The patient had taken the usual tonics, also quinine in large doses, and acetanilide, without relief. The pain was severe in the areas supplied by the infra-orbital, the supra-orbital, the temporo-malar, and the great occipital nerves, also in a spot a little to the left of the seventh cervical vertebra. There was no tenderness along the spine. Complete relief followed the injection of several drops of a fifty per cent. solution of carbolic acid at the points from which the pain radiated. Two weeks had passed, at the date of Dr. Garst's letter, without any return of the pain, and during that time trinitrin had been taken.

Infantile Diarrhœa.

At a meeting of the Harveian Society of London, held November 7, 1889, and reported in the *Medical Press and Circular*, November 20, 1889, Dr. Luff read a paper on the causation and the treatment of that variety of acute infantile diarrhœa produced by irritative products, resulting from fermentations set up in milk, either previous to or after ingestion. While admitting that though probably several irritating substances resulting from the fermentation of milk are factors in the production of the form of acute infantile diarrhœa under consideration, he contended that the principal share of blame rests with milk or cheese ptomaine tyrotoxicon produced during the fermentation of milk under certain conditions. The treatment of acute infantile diarrhœa, with the view of arresting the abnormal intestinal fermentation was then considered. Carbolic acid, creasote, resorcin, salicylic acid, salicylate of soda, naphthol, and salol have been given in the hope of checking the putrefactive changes in the bowels. Ringer has recommended the administration of a weak solution of bichloride of mercury in infantile diarrhœa attended with very slimy stools. Dr. Luff then referred to Illingworth's antiseptic treatment of infantile diarrhœa, which he had himself found most useful, and the employment of which had first directed his attention to the treatment he had employed. This consists in drug treatment and diet treatment combined. The drug treatment consists in the administration of one-fiftieth of a grain doses of the biniodide of mercury dissolved in iodide of potassium, combined with one grain doses of chloral hydrate. It was shown experimentally that the biniodide of mercury is an extremely soluble and diffusible salt, and that it possesses the property of combining with and rendering insoluble the milk ptomaine tyrotoxicon. As regards the diffusibility of the biniodide of mercury, Dr. Luff has detected it in the urine within two hours of its administration. Dr. Luff had never found that soluble biniodide of mercury itself acts as an intestinal irritant. Of eighty cases of acute infantile diarrhœa treated in this method the diarrhœa ceased within two days in seventy-two of the cases,

in five out of the remaining eight cases it ceased within four days, and in no case did it last over seven days.

Fractures of the Base of the Skull.

Fracture of the base of the skull has been one of those injuries which the surgeon has treated purely upon the expectant plan, and with the conviction that death is sure to follow. This view of the lesion has been entertained for years by hospital surgeons, and there is certainly a consensus of opinion among surgical writers in regard to the prognosis in this injury. All the standard text-books and monographs are in accord in reference to the mortality.

Dr. Frederic S. Dennis, of New York, in an interesting paper on this subject, read before the New York Academy of Medicine, and appearing in the *Medical Record*, November 23, 1889, claims that it is a clinical fact that the great majority of these cases die from causes which can be wholly prevented by the surgeon. There has been but little encouragement to the medical man to attempt any treatment in these cases of basilar fracture, when one reads, as he may, in the latest edition of a large standard work on surgery, "that any treatment directed to the lesion itself is out of the question."

The fractures of the base of the skull may be situated in any of the three fossæ of the cranium. They may be divided into three varieties :

1. Where the fracture involves the anterior fossa, the roof of the orbit, or the nasal cavity.

2. Where the fracture involves the middle and posterior fossæ.

3. Where the fracture involves the posterior fossa.

The first variety is seen in falls upon the forehead, or by an umbrella or cane thrust through the roof of the orbit.

The second and third varieties, where forces act from below, as a fall from a height where the patient strikes upon the tuberosities of the ischium or upon the vertex of the skull.

The signs and symptoms of fracture of the base of the skull slightly vary according to the seat of the injury. There are, however, three signs and symptoms that are nearly always present. These are, first, hemorrhage; second, escape of cerebro-spinal fluid ; thirdly, coma. In regard to hemorrhage, the source of it is most important to consider. If the anterior fossa is the seat of fracture, the bleeding occurs from the nose or from the mouth, and usually there is subconjunctival ecchymosis ; if the middle and posterior fossæ are involved, the hemorrhage is from the ear and occasionally from the nose. It must be noted that, in cases of non-rupture of the membrana tympani, the blood may escape into the nose and pharynx and enter the stomach. Hemorrhage in such a case may exist but there are no external evidences of it. The first intimation that the surgeon has of the existence of hemorrhage is hematemesis. Absence, therefore, of hemorrhage from the ear or nose is not conclusive evidence of the non-existence of a basilar fracture. On the other hand, the presence of bleeding alone from the ear is not in itself a diagnostic sign of any value as indicative of fracture of the base of the skull.

The escape of cerebro-spinal fluid is a valuable diagnostic sign. Coma is also present in a greater or less degree, according to the severity and the situation of the fracture.

With a view to simplifying the general subject of basilar fractures, Dr. Dennis advances the two following propositions :

First. That fractures of the base of the skull should be considered in the same category as compound fractures of the vertex of the skull or long bones.

Second. That since fractures of the base of the skull possess the same essential characteristics as other compound fractures, they should therefore be treated by the same exact principles of aseptic surgery.

Dr. Dennis answers the first proposition by stating that the entrance of air to the seat of a fracture is a *sine qua non* for the existence of a compound fracture, and that the same applies to basilar fractures, since the air may gain access to the seat of the fracture either through the external auditory meatus, the Eustachian tube, or through the pharynx or nasal cavities. Then again, basilar fracture is associated with hemorrhage, laceration of the nerves, with venous thrombosis, with septic phlebitis, with fat-embolism, with cerebro-spinal shock, with pyemia —in fact, with all the complications that arise in other compound fractures.

The essential features of the treatment should therefore be the same as for any

compound fracture, viz.: Antiseptic cleansing of the wound, immediate immobilization, proper drainage, and permanent fixation. Dr. Dennis then shows how these principles may be applied to basilar fractures. The technique is simple. The patient suffering from fracture of the base of the skull, should be removed to the operating room, and every outside preparation having been made to make the toilet aseptic, the head should be held firmly and the entire scalp shaved, after which it should be thoroughly washed with soap and water, and then irrigated with a 1 to 500 bichloride of mercury solution. Attention should next be directed to the irrigation of the external auditory canal and the nasal cavities. Both of these should be rendered thoroughly aseptic, after which the ears should be packed with iodoform or bichloride gauze and some absorbent cotton plugs placed in the nose. The air can filter through cotton, but microorganisms cannot pass through it. In irrigating the nasal fossæ the surgeon must exercise great care, lest the fluid enter the stomach and produce toxic effects. There remains now only one other possible channel of infection to the seat of fracture, and that is the Eustachian tube. This may carry sepsis to the interior of the cranial cavity in a fracture of the base.

In the ordinary form of fracture of the base, where the membrana tympani is ruptured, the discharges make their exit through the auditory canal. In the exceptional cases where the membrane is not ruptured, the blood, serum, and cerebro-spinal fluid find their way into the nasal cavity and the pharynx, and thus these cases are most exposed to sepsis. If the unruptured membrana tympani is examined in a basilar fracture, the membrane will be puffed out on account of the presence of fluid behind it, and the membrane will have lost its natural lustre. These are the circumstances under which it may be wise to puncture the membrana tympani, and thus allow the blood and the cerebro-spinal fluid to escape through the external auditory canal. The diversion of the discharge from the Eustachian tube into the ear makes it possible to keep the fluids permanently aseptic. Having now rendered the head and all the avenues of approach to the intracranial cavity aseptic, it remains to apply a dressing that will keep these parts permanently free from any source of infection. This object is best accomplished by the use of a cap made of wet loose bichloride gauze or carbolized wool, over which absorbent cotton should be placed and a bandage applied. The cap should completely surround the entire head, cover in the ears, and protect every channel leading down to, and communicating with, the seat of fracture, and the cerebral viscera from the entrance of septic germs. This same dressing should be made from time to time during the repair of the fracture, and under the same strict and rigid rules of antiseptic surgery. The head should be held firmly by some dressing that insures its fixation and keeps the fracture as quiet as possible during the repair.

The practical value of Dr. Dennis's theories is ably demonstrated by the report of a case of severe basilar fracture, which, although accompanied by most unfavorable complications, resulted favorably under the treatment above described.

Nitrous Ether for the Cure of Eczema Inpetiginodes.

Dr. W. H. Sullivan, of Rising Sun, Ind., writes to the *Cincinnati Lancet Clinic*, Dec. 7, describing the curative effect of sweet spirits of nitre upon an eczematous affection of his face and hands. The disease began about ten months ago, and was treated by the most approved methods, without much success.

When about despairing of any good results, Dr. Sullivan was handling some nitrous ether, which was spilled on the affected parts. It produced immediate comfort, relieving the itching and gradually the discharge from the skin ceased. When itching or burning again occurred a thorough application was made of the nitrous ether, and after a lapse of three weeks he describes the results as simply marvelous.

The writer is a physician of forty-one years' standing, a graduate of Transylvania University.

Hygiene and Sunday.

Among the questions treated of at the recent Congresses in Paris, that of the observance of the Sabbath as a day of rest was not the least interesting. The Congress on this subject was presided over by M. Léon Say, who remarked that this rest, which several religions rendered obligatory, is a law of nature, and consequently a law of hygiene,

the excellence of which has long been demonstrated, although it is not to be found in all national codes. The resting on the seventh day is of Biblical origin, and the custom of counting the days by seven was formerly the rule among the most diverse races —in India, as among the Celts, in China as well as in Arabia. Now that hygiene has become a positive science, it confirms the moral and material necessity for a temporary rest on the seventh day. The idea was adopted in principle by all the members of the Congress, which received the patronage of two political celebrities—Mr. Harrison, President of the United States of America, and Mr. Gladstone. In a letter which was read publicly, President Harrison declared that he considered that all workers, whether with the hands or with the head, were in need of rest, which alone can guarantee the general observance of the Sabbath. Mr. Gladstone declared that he attributed his robust health and his longevity to his invariable observance of the Sabbath rest. Several reports were presented to the Congress, and physicians, professors, philosophers, and hygienists are in accord on this point. All, without exception, support for workers of all classes and of all ages a weekly day of rest, which should even be made obligatory. It may here be noted that in 1881 this subject was opened to competition by the Swiss Government for a prize, which was awarded to Dr. Niemeyer, of Leipsic. The subject was brilliantly treated by Dr. Niemeyer, who observed that the Dominical rest is the first commandment of hygiene, which should be followed to obtain a peaceful and continued amelioration of society, and in this respect it is as much a rational institution as a religious one. The following is the summary of the conclusions voted by the great majority of the members of the Congress:—"Rest on Sunday is possible in varying degrees in all industries. Sunday is the day which best suits the employer and employed, both as regards the individual himself and his family, and it is well that the day of rest should be, as much as possible, the same for all. When the Sunday rest is impracticable for certain reasons, it should be replaced by some other day, so that the workman may have fifty-two days' rest in the year as equally divided as possible. This rest permits man to produce considerably more and better work, inasmuch as it contributes to maintain his zeal and to restore his physical forces."—*Lancet*, Nov. 23, 1889.

NEWS.

—The death-rate in New York last week was the lowest ever reached, being only 18.20 per cent. per 1,000 population.

—The Corporation of Dublin has adopted the Infectious Diseases Act, which compels notification of contagious and infectious diseases.

—All the schools in Marlboro, Massachusetts, were closed Dec. 11, owing to the prevalence of diphtheria. Twenty cases have been reported.

—The sum of $800,000 has been bequeathed by the will of the late Mr. J. H. Schoenberger, to found a hospital for incurables at Pittsburgh, Pa.

—Dr. Charles P. Noble has been appointed Surgeon in Charge of the Department for Diseases of Women, at the Northern Dispensary, Philadelphia.

—On November 26 the medical department of the Dartmouth Medical College held its annual commencement. The graduating class numbered twenty-one.

—Dr. Remsen Taylor, the health officer of Long Island City, who has been under investigation for extortion, by the Grand Jury of Queens County, has received an official vindication.

—A Detroit physician, who is dying from necrosis of the frontal bone, is reported to be watching his own case without other professional aid, taking copious notes of the symptoms, etc., as they appear.

—Dr. E. H. Wright, a well-known and highly-respected physician of Georgia, and for many years a subscriber to the MEDICAL AND SURGICAL REPORTER, died at his home, Latilla Bluff, December 4, 1889.

—Professor Thomas Opie, Dean of the College of Physicians and Surgeons, in Baltimore, is reported critically ill from blood poisoning, contracted while performing a surgical operation a few weeks ago.

—Drs. F. S. Powell and R. C. Word, who for many years have been editors of the *Southern Medical Record*, have retired from the editorship, having sold their interest in the *Record* to Dr. D. H. Howell, of Atlanta, Georgia.

—Dr. Hans Virchow, Privatdocent in the University of Berlin, and Prosecutor in the Anatomical Institute, has been raised to the rank of Professor Extraordinarius. Dr. Hans Virchow is a son of the celebrated pathologist.

ENTERED AS SECOND-CLASS MAIL MATTER AT PHILADELPHIA P. O.

PARIS MEDAL
TO
WILLIAM R. WARNER & CO.

W. R. WARNER & CO. have received a Silver Medal at the Paris World's Fair, being the highest of its kind, in recognition of the following claims:
First.—W. R. Warner & Co.'s Pills, quick solubility and accuracy.
Second.—Reliability and permanency unsurpassed. Also for Warner & Co.'s Effervescent Salts.
First.—Superior effervescing properties.
Second.—General elegance, excellence, and stability.

PHYSICIANS SHOULD BE CAREFUL TO SPECIFY WARNER & CO.

☞The coating of the following pill will dissolve in 4½ minutes.☜

PIL: CHALYBEATE COMP.
(WARNER & CO.)

Nux Vomica is added as an ingredient to Pill Chalybeate to increase the tonic effect when desired.
Composition of each Pill.—℞ (Chalybeate Mass.), Carb. Protoxide of Iron, gr. 2½. Ext. Nuc. Vom. gr. 1-6.

DOSE—1 to 3 Pills.

Most advantageously employed in the treatment of Anæmia, Chlorosis, Phthisis, Scrofula, Loss of Appetite, etc.

PIL: ANTISEPTIC.

Each Pill contains: Sulphite Soda, 1 gr. Salicylic Acid, 1 gr. Ext. Nuc. Vomica, ¼ gr.

DOSE—1 to 3 Pills.

Pil. Antiseptic is prescribed with great advantage in cases of Dyspepsia attended with acid stomach and enfeebled digestion following excessive indulgence in eating or drinking. It is used with advantage in Rheumatism.

Prepared by WM. R. WARNER & CO.

PIL: ANTISEPTIC COMP.
(WARNER & CO.)

Each pill contains: Sulphite Soda, 1 gr. Salicylic Acid, 1 gr. Ext. Nuc. Vomica, ⅛ gr. Powd. Capsicum, 1-10 gr. Conc't Pepsin, 1 gr.

DOSE—1 to 3 Pills.

Pil. Antiseptic Comp. are prescribed with great advantage in cases of Dyspepsia, Indigestion, and Malassimilation of Food.

Supplied upon physician's prescription by all leading druggists. Take no substitute.

BURN-BRAE.

This Hospital, founded by the late R. A. Given, M.D., 1859, and designed for the care and treatment of a limited number of cases of **Mental** and **Nervous Disorders**, is located at Clifton Heights, Delaware Co., Pa., a few miles west of Philadelphia. Primos Station, on the Philadelphia and Media Railroad, is within less than ten minutes' walk.

Burn-Brae has been in operation for more than a quarter of a century, and numbers its friends in all sections of the country. With **extensive grounds**, handsomely laid out, building attractive in appearance, a wide and varied view, bedrooms large, cheerful, and well furnished, heating-facilities perfect, light abundant, with constant professional supervision, Burn-Brae offers, for the care and treatment of its inmates, a pleasant, safe, and healthful Home.

Resident Medical Officers:
J. WILLOUGHBY PHILLIPS, M.D., S. A. MERCER GIVEN, M.D

FRACTURE OF THE NOSE.—TALIPES.—INJURY TO THE SHOULDER.—COLLES'S FRACTURE.—HERNIA CEREBRI.—FOREIGN BODY IN THE FINGER JOINT.—THE STROMEYER SPLINT.[1]

BY JOHN H. PACKARD, M. D.,

VISITING SURGEON TO THE PENNSYLVANIA HOSPITAL.

Fracture of Nose.

Gentlemen: This patient is one to whom I wish to call your particular attention, because he presents a condition not often seen in a clinic. This man has a contusion of his eye, and upon this side of his bruised and swollen nose I feel distinct crepitus. Often the so-called cases of fracture of the nose are really displacements of the cartilages of the nose from the nasal bones, the line of articulation being found just above the pad of the ala, the supposed fracture being merely a separation of the parts. I feel here, however, the crackling of the fragments, and I wish to ascertain whether or not the bones are in their proper position. In order to do this I take a grooved director, choosing this instrument on account of its firmness, and pass it up the nose and close to the septum, thus avoiding the upper turbinated bones. I find the fragments almost exactly in position. Had they been displaced, I should have taken a roll of carbolized lint and plugged the nostril, thus pressing the bones into place and holding them there. In treating cases of this kind, frequently the separation of the cartilages is not properly replaced, and as a result there is a permanent disfigurement. The vomer and the perpendicular plate of the ethmoid bone are not disturbed in this case, but there is merely a cracking of the nasal bone upon this right side. No disfigurement will result.

[1] Delivered at the Pennsylvania Hospital.

In examining the nose, you see I have produced quite a free hemorrhage. A common error is to draw cold water or ice-water into the nose to stop the bleeding. Hot water is a much better hemostatic, and we will use it here.

Talipes.

I now show you this case of varus which has been brought here for operation. The patient is a colored girl who states that she is eleven years old. When I show you the condition of things here, it appears as if we could do something for this ankle by taking out the astragalus or the cuboid bone and thus bring the foot down so that she would be able to walk. But when I show you her knee, you see that it is in a state of actual dislocation. The head of the tibia fits against the back of the condyles of the femur and there is a new joint surface on the posterior surface of the condyles instead of at their extremities. I could remedy this also, but if I did, I should have here another condition to confront, namely, a wasting of the glutei muscles. There is a flatness of this hip, and the trochanter, which should be like that of the other side, can scarcely be seen; and when I rotate the limb, the arc of rotation of the trochanter is very slight, showing that the neck of the bone is short, and the head of the bone very small. The upshot of all this is, that some cases of deformity may be remedied, but the results obtained would not justify the necessary operative procedures, as there would not be enough accomplished towards the bettering of the condition, and making the limb useful, to warrant the operation. This case is one of this class, and the advice I would give to the child's parents would be that she be allowed to continue the use of her crutch, and that they should not subject her to an operation.

Injury of Shoulder.

I now show you a child who has been before you once or twice before. The case is one of an injury to the shoulder in which suppuration of the joint had occurred; and it was decided on full consultation with my colleagues that an excision of the upper portion of the bone should be performed; but the case has improved so greatly under treatment that I postponed operation indefinitely and shall merely dress it before you to-day. To do this I employ this zinc cap for the shoulder, which gives support to the parts and holds them in place. This should not be carried too far over the shoulder, or else it will defeat the object you wish to accomplish, namely, the holding of the head of the humerus in place. If the cap extends too far over, it rests upon the clavicle, and does not affect the humerus at all. This cap just reaches to the point of the shoulder, as you see. An injury like this in an adult would probably have much more serious results than it does in this child. In making the shoulder cap, cut the zinc larger than you need, and then turn it down and trim it to suit your case. You see, it holds itself in position. It is turned so as to fit nearly to the axilla anteriorly and posteriorly, and over the shoulder. There is a considerable degree of motion in this shoulder joint. There is no fracture of the joint here, but of the surgical neck of the humerus, and there is a little dead bone present, but if the opening will heal up, I will not interfere with it. I will replace the splint and show you the patient some time again. This is a very instructive case, and I believe the boy will get entire freedom of movement in the joint.

Colles's Fracture.

The next case is an old woman with a Colles's fracture. The most essential point in the treatment of this fracture is the reduction. If you do not reduce it you get a poor result, no matter what appliances you may use. I applied to this a Levis's splint, which is a very excellent form. There is a very slight deformity here, but not enough to make any material difference, especially as the woman has naturally a prominent ulna, and one of the remaining traces of every Colles's fracture, is a projection of the ulna. In this case the natural condition must be taken into consideration. There is about the same amount of dropping of the two wrists. In some cases of this injury, the fragments may remain in place, no deformity result. But if you have a persistent tenderness in the bone, you may be certain that there is a fracture. One word in regard to the splint. It is a matter of great consequence that you get a splint of the right size. You might as well run a man's foot into a child's boot as to put his limb into too small a fracture apparatus, while if the latter be too large, it will not hold the limb securely. In case of any fracture, if the patient leaves your hands with the

slightest avoidable deformity, just so far have you failed in your duty. There are cases in which shortening will necessarily occur, as in delirium tremens or to a disobedient patient, but usually it can be prevented.

Cerebral Hernia.

I now show you the case I had before you two weeks ago, the man with a fracture of the skull just over the ear involving the temporal and parietal bones. As you will remember I removed a large fragment of the bone. There was a copious hemorrhage which I stopped by means of a plug of iodoform gauze, but it recurred, and we were obliged to re-dress the wound and insert a new plug. After this he had several very violent unilateral convulsions due, probably, to the pressure of this plug. Twice his temperature rose to 101° and a little over. You now see the wound. When I speak to the man you notice how slow and thick his speech is. This can be accounted for if you notice the position of the wound, which is upon the left side of the head close to the centre of speech. There was a loss of the substance of the brain, and I had to explore the cavity to remove fragments of bone. This loss has been attended with a degeneration of the surrounding brain tissue, involving a portion of the island of Reil, and consequently his speech is very imperfect. He sleeps almost constantly, and lies without noticing anything. You notice there is considerable swelling here, and a hernia cerebri has formed. No matter how much pressure we make upon this, it will grow. Nevertheless we shall continue our pressure upon it in the hope of stopping its growth. He is very dull, as you see, and I do not believe he has uttered a sound since the injury was received, except when disturbed by urgent questioning. His color is good, pulse slow, temperature normal, and there is a possibility we may be able to control this hernia cerebri, and the man recover. Two years ago I had a case before you in which there was a severe injury to the top of the head with an enormous loss of brain substance. The man recovered without a symptom and wanted to go out of the house in the course of a week, but was dismissed at the end of three weeks cured. This shows how a considerable amount of the brain substance may be removed with apparently no bad results. This wound was dressed entirely antiseptically, and yet you see there has been a discharge. This is not pus, but degenerated brain substance. It is an interesting fact that often cases, in which there is a most trivial wound of the brain, will die, while those in which there is a terrible injury will recover entirely. You will recall, for instance, the celebrated case in which a crowbar was driven through the brain, but the man got well. It is important to remember this fact; you should never neglect an injury of the head however slight. If there be any shock attending the injury, never regard it as trifling, for there has been a concussion or commotion of the brain-substance. [This patient is now, November 15, almost entirely well.]

Foreign Body in Finger-Joint.

This man has had a small iron pin driven into his finger-joint by some machinery. He has now a marked degree of arthritis, and believes that the pin must have been left in the joint. I will proceed to open the joint; I shall do so simply to treat the arthritis, with the expectation that the man will have a perfectly movable finger. This operation, which is one of the modern improvements in surgery, will prevent the further progress of the trouble. We are now able to open joints, wash them out, and close them antiseptically. It seems as if this injury of the finger is a small affair, but when we consider that the man's livelihood depends upon the condition of his hand, it becomes a matter of greater importance. Should this operation fail, and he recovers with a stiffened joint, he is then no worse than he would have been were the case allowed to run on, and his condition then could be relieved by amputation. I wish to avoid dividing the tendon or injuring the vessels, and to do this I make my incision at a point between the extensor tendon and the side of the finger, that is, along what I should call the corner of the finger. I make the incision an oblique one, so as to get the most complete closure afterwards. The pin is here. It seems a simple thing to take out a foreign body embedded in the tissues, but it is often a matter of great difficulty. This pin had partly penetrated the bone. I will wash out the joint, and will place the finger upon a straight splint, after ligating all bleeding points, and inserting a small drain. [Complete restoration of the mobility of the joint resulted in this case.]

Stromeyer Splint.

I wish to dress this case of elbow trouble before you to show you the use of the Stromeyer splint which is an apparatus devised to preserve the mobility of the joint. This man, when he entered, had scarcely any power of flexion in his arm. I divided the tissues just over the most prominent part of the lower fragment, which I chiseled away, and dressed the wound with the arm at a right angle. If I did not want to get motion here, I should not remove the dressing. There is not much motion here now, but by manipulation I can secure a certain amount of motion in the way of flexion and extension, and slightly in pronation and supination with which I will be satisfied at present. I shall again apply the Stromeyer's splint adjusting the angle by means of these screws to the new angle in which I have placed the arm. I hope, by means of this splint, to save this man the use of his joint. [This patient was shown to the class four weeks later, with the power of flexing the elbow to less than a right angle, and with almost perfect pronation and supination.]

COMMUNICATIONS.

CYSTIC TUMOR FORMED BY HERNIA SAC.

BY C. L. BOWER, M. D.,

ADJUNCT PROFESSOR OF CLINICAL AND OPERATIVE SURGERY IN THE PHILADELPHIA POLYCLINIC, ASSISTANT SURGEON TO ST. AGNES'S HOSPITAL, AND SURGEON TO ST. CLEMENT'S DISPENSARY.

A woman with the following history recently came under my care:

Sarah E. D., 45 years old, while washing clothes eight years ago, suddenly felt something give way in the lower part of her abdomen on the left side, and found that she was unable to walk, on account of pain and weakness. On examination she discovered a tumor, about the size of her fist, in the left inguinal region. It was diagnosticated an inguinal hernia by her physician, who undertook to reduce by taxis. He only succeeded after three hours' work, the patient being under ether. A truss was then applied, which the patient wore without any discomfort until one year ago when it began to give her such pain that she was compelled to stop using it. After a little while she found that she could not reduce the hernia. The pain continued at intervals and caused her considerable inconvenience.

When she first came to me for treatment, I found, on examination, a tumor, about the size of a goose egg, in the left inguinal region, protruding from the external ring. The growth was irreducible and caused her some pain on pressure. It was apparently an incarcerated hernia. An operation was therefore advised, to which the patient consented.

She was etherized and prepared aseptically, and every precaution taken throughout the entire operation to insure asepsis. An incision about three inches long was made directly over the tumor, and the tissues dissected away until the sac was reached. This was pear-shaped, the neck completely filling the external inguinal ring. After carefully enucleating the sac, I prepared to open it. Although there was no gut to be felt, there appeared to be a small piece of omentum, which would not go back into the abdominal cavity. On opening the sac nearly six ounces of straw-colored fluid escaped, and on exploring the sac found that there was no opening into the bowel. Attached to the upper part was an irregular piece of tissue, two and a half inches long, which hung down into the cavity of the sac, resembling a mass of inflammatory tissue or altered omentum. The pedicle was then ligated, the sac removed, and the wound closed with catgut sutures, and a dry gauze dressing applied. The wound healed by first intention and the patient has had no further trouble.

The case, in my mind, is evidently one of an old hernia cured by pressure of the truss, which, however, excited an inflammation at the neck of the sac, causing the tissues to become painful. The walls of the sac, included in the inguinal canal, being pressed together by the truss a plastic inflammation was set up which permanently closed it. The sac thus formed remained a simple cyst.

—An operation to relieve paralysis of the lower part of the body, resulting from fracture of the spine, was performed by Dr. Thomas G. Morton at the Pennsylvania Hospital a few days ago. Dr. Morton says he has performed two operations of the same nature, with a fair degree of success.

CREMATION.

WHAT IS THOUGHT OF IT BY PHYSICIANS.

INTERVIEWS WITH PHYSICIANS BY A REPRESENTATIVE OF THE MEDICAL AND SURGICAL REPORTER.

SECOND SERIES.—PHILADELPHIA.

DR. ALFRED STILLÉ, although confessing that he had not given the matter much study, and did not care to express any very strong opinions on the subject, said that the only hygienic way in which the bodies of the dead can be disposed of is by their entire destruction, as far and as quickly as possible, whether this is done by cremation or otherwise. Cremation is, of course, most practicable. Inhumation is, without doubt, a most insanitary custom. Both in England and in this country several epidemics—especially of typhoid fever—have been traced to ground pollution. Dr. Stillé said that all countries adopt the most convenient and natural method for the disposal of their dead. Thus in Egypt, where burial on the banks of the Nile was forbidden for fear of river pollution, where burial in the shifting sands of the desert was impossible, and where the scarcity of fuel precluded cremation, mummification, or embalming, was adopted. In India, where fuel abounded, cremation is still a common custom. Here in America, on account of the vast extent of ground, inhumation had become popular. The disposition of his own body is a matter of indifference to him. Regarding his family, sentiment and custom would lead him to burial rather than to cremation. Although fully alive to the benefits obtained by cremation, Dr. Stillé does not think that at present the wholesale introduction of cremation into our United States is of pressing necessity.

DR. JAMES H. HUTCHINSON said he had little to say on the subject, and it was with difficulty that our representative could induce him to say even that. Dr. Hutchinson evinces the stereotyped indifference regarding the fate of his own mortal remains. He admits the superiority of cremation over inhumation from a sanitary point of view. He thinks that city burials as well as burials on the banks of rivers that furnish the public with water supply are undoubtedly injurious to the public health. In his opinion it will be hard to reconcile the public to cremation. Regarding the argument that has been advanced in opposition to cremation, viz., that the tracing of poisons will be impossible, he thinks it of but slight importance. Where any suspicion existed the bodies could be retained for a reasonable length of time. Some poisons, also, such as arsenic, could possibly be traced in the ashes even after cremation.

DR. JAMES W. HOLLAND was next seen, and our representative was entertained by a most interesting account of the crematory in Milan, which Dr. Holland had visited and which had made a deep and most favorable impression upon him. Æsthetically, cremation seems to him most beautiful and impressive. There is absolutely nothing distasteful or revolting about the procedure, and no room is left for improvement. The crematory at Milan is a most imposing structure, and stately in its architecture. On each side of the main building is a lofty marble columbarium. The spaces between the columns contain niches for the reception of the urns of ashes. Some of these spaces belong to families, who have erected in them altars, surmounted with beautiful groups of sculptured marble. The larger spaces belong to various Societies or Orders, and are ornamented with appropriate groups or designs in marble. Every surrounding corresponds with this æsthetic refinement and solemn beauty. The grounds are most beautifully and tastefully laid out, and all the unpleasantness which we naturally would associate with the disposal of the dead is absent. Dr. Holland thinks that in many instances inhumations are a source of ground pollution. In Florida and Cuba this fact is most prominent. It is also an acknowledged fact that, where the remains of cattle which have died from cattle plague or splenic fever are buried, the ground becomes so impregnated with the diseased germs, that other healthy cattle, browsing over these sites, invariably contracted the disease. "True," said Dr. Holland, "we do not 'browse' in cemeteries, yet we frequently use them as pleasure resorts, and even this cannot be entirely devoid of danger." He then spoke of the evils of city graveyards, and also of the importance of the cremation of all bodies having died from infectious or contagious diseases. The only possible objection to cremation is the inability to trace poisons in criminal cases. In the heat of the cre-

matory even arsenic would be sublimed and carried off in vapor form. It is an undeniable fact that, since it has become universally known that arsenic can always be traced in the body if present, the number of cases of arsenical poisoning have considerably decreased. Regarding the disposition of his own remains he had no choice or feeling, but would leave this entirely to the feelings or sentiments of his family, who in all probability will bury him.

Dr. Hannah Croasdale was found to be staunch in her approval of cremation. She is of the firm opinion that the day is not far distant when cremation will become a universal custom in this country. Dr. Croasdale looks eagerly forward to such a future, for both hygienic and sentimental reasons. The value of cremation from a sanitary point of view is unquestionable. Æsthetically one can make as much ado over the ashes of one's departed as over their bodies. Personally she would make no provision for the cremation of her own body, on account of custom and usage, but would leave its disposition to her children. She believes that in certain localities burials without doubt pollute the ground.

Dr. James C. Wilson was also found to be an upholder of cremation. He believes it to be the only hygienic method for the disposal of the dead. Inhumation is undoubtedly a source of ground pollution. He is of the opinion that the prevalence of typhoid fever in Philadelphia is very possibly due to the contamination of the Schuylkill water supply by filtrations from the Laurel Hill Cemetery. Dr. Wilson does not think cremation will ever become general in this country, on account of the theological objections to it. Many devout Christians cannot reconcile themselves to it. Personally he would prefer to be cremated rather than buried.

Dr. R. M. Girvin decidedly favors cremation. He said that he had influenced several of his patients to have their bodies cremated. It is his opinion that cremation is the only truly hygienic method for the disposal of the dead. Regarding the disposition of his own body, Dr. Girvin evinces the characteristic indifference of medical men. As to his family, he would have no compunction in cremating them, but, merely from usage, until cremation became more universal he would probably bury them. He does not lay much stress on ground pollution, and thinks that very little danger to public health is incurred in this way. He hopes that cremation will ultimately become a universal custom, and is, from a sanitary as well as sentimental point of view, in accord with it.

Dr. Anna E. Broomall confessed an entire absence of opinion on the subject and could not be induced to commit herself either one way or the other. She said that, if she had had any personal experience with cremation she would have been pleased to tell our representative about it; but this not having been her good fortune she had nothing of interest to say.

Dr. J. Solis Cohen warmly supports cremation, and would greatly desire the cremation of his own body, although he had made no provision to this effect, on account of the feelings of his family. Apart from a sanitary point of view, he thinks that the introduction of cremation in this country should be urged on account of the cupidity of the churches, if for no other reason. He has seen in this city, time and again, churches of various denominations sell their edifices, grounds and graves to make room for factories or business houses. In these cases the remains were cast up by the workmen and open to the gaze of the public. Cemeteries and churchyards that are now suburban may, in the course of a few years, be in the heart of the city, and may possible be treated in the same manner. So, for the one reason of desiring to guard against a possible future desecration of his remains, he favors cremation. Hygienically, Dr. Cohen thinks there can be no question as to the superiority of cremation over any other present method for the disposal of the dead. Dry ground is an excellent disinfectant and purifier, but moist or wet ground can certainly become polluted through inhumation. Dr. Cohen fears that cremation will not become popular in our day; for, he says, it takes many years to change the customs of a people. Yet he earnestly hopes that the matter will be pushed and the introduction of cremation urged without delay.

Progress of Cremation.—There are now thirty-nine crematories in various parts of the world. Italy has twenty-three, America has ten, while England, Germany, France, Switzerland, Denmark and Sweden have one apiece. Since 1876 the cremations in Italy have been 1,177, and the total elsewhere only 1,269.

FOREIGN CORRESPONDENCE.

LETTER FROM BERLIN.

Enchondroma of the Vertebral Column.—Carcinoma of the Stomach.—Trichomycosis nodosa.—Antiseptic Cologne.—Smokeless Gunpowder.—Magnesite Plates.—Varia.

BERLIN, November, 1889.

The Berliner Medicinische Geselleschaft has reopened its interesting weekly meetings. At a recent meeting the venerable President, Professor Virchow, showed a rare specimen of enchondroma of the vertebral column. It was taken from a living man sixty-five years old, and is remarkable both for its size and its locality. The tumor measured 29 centimetres, and was removed from its nidus, covering the seventh and eighth ribs, with the sharp spoon. The man had first noticed eight years ago a swelling of the size of a plum, about 2½ inches to the left of the vertebral column. He had been unable to walk for years, and since the middle of this year had shown vesical paralysis and other spinal symptoms.

Another interesting specimen shown by Professor Virchow was one of carcinoma of the stomach. A resection had been performed by Professor Bergmann, and the patient had been discharged as cured in the beginning of August. Two weeks ago, however, he had been suddenly seized with violent gastric pain, and had to be admitted to the Charité. The autopsy revealed an extensive carcinomatous tumor which, however, on account of its peculiar locality was almost completely out of reach of palpation. The tumor lay near the lesser curvature of the stomach and had implicated the left supra-renal capsule and the solar ganglion. The cicatrix formed after the resection presented very favorable conditions.

Dr. Behrend made some interesting remarks on trichomycosis nodosa, of which affection he presented a specimen. He defined the affection as a morbid condition of hair characterized by the formation of little nodes. If such hair is drawn through the fingers, a roughness and unevenness is felt. The affection has hitherto been known chiefly by the name of Osorio's piedra, on account of its having been first described by the Spanish physicians of the U. S. of Columbia. Regarding the results of microscopical examination, a great variance of opinion seems to exist. The view of Dr. Behrend is that the little nodes do not consist of epithelial cells but of bacillary spores which surround the hair without being able to penetrate into its interior.

The field of preventive therapeutics is steadily growing, as can be seen from the many gratifying pharmacal innovations in the line of antiseptic agents. The latest acquisition in this respect is one which is intended to benefit more the attending physician and relatives of the patients, than the patient himself, viz., antiseptic Cologne. The preparation is gotten up in bottles, on the principle of the Cologne atomizers, and is really a useful and convenient agent. The physician is supposed to carry a miniature bottle of antiseptic *Eau-de-Cologne* about his person and to sprinkle his clothes and person with this agreeable and at the same time germicidal solution before leaving the sick-room. The relatives of the patient, on the other hand, can use the Cologne for the floor, furniture, bed-clothes, urine of the patient, etc.

Your correspondent attended recently a meeting of the Berlin Polytechnical Society and obtained quite a number of interesting scientific data from it. A discussion about the so-called smokeless gunpowder, to be shortly introduced into the German and Austrian armies, was all the more interesting to me as a month or so ago I had watched the latter in action during the manœuvres of the Prussian Gardes. The invention is claimed both by an Austrian officer and Dr. Schneider, a chemist of Berlin. The composition of the powder is a State secret, and is consequently unknown to the public. It seems, however, to be tolerably sure that both gun-cotton and nitro-glycerine are among its components. The name of smokeless powder is not quite an appropriate one, as smoke is not wholly absent, but simply lessened very materially in quantity. The effects of this powder which I noted during the manœuvres were rather surprising. It was evident that in many instances the troops were wholly at a loss to indicate the direction from which the shooting proceeded. The general impression here is that the smokeless powder will greatly intensify the sacrifices and horrors of the coming wars.

A member of the Polytechnic Society presented some specimens of what he termed magnesite plates, a new material which is said to present distinct advantages as a covering material for floors, walls and roofs.

Magnesite is a hard substance, of light specific gravity, incombustible and absolutely impermeable by dampness. The latter property places magnesite at once in a favorable hygienic light. But there is still another virtue in magnesite, which will render floors covered with it a blessing to many persons, particularly in German cities. Magnesite deadens the sound almost completely, and will be quite useful in German flats with one or two pianos on each floor.

Of interest also was a paper read by a member, in which he endeavored to show that carbonate of sodium, if added to the water used for making coffee, improves the latter considerably. The reason of this improvement the lecturer placed in the greater solubility of caffeine in water in which some carbonate of sodium had been dissolved. I think it is time that something should be discovered to improve the German coffee. I, for my part, am quite sure that I have not obtained a good cup of coffee since I left America. There is, besides, but little coffee and still less tea drank in the Vaterland, beer being the general drink. This beverage in its pure and nutritive state in which it is obtained in Germany appears really preferable to the strong teas and coffees indulged in in America. To be sure this point is open to argument. The question also arose in the Polytechnic Society whether salicylic acid and glycerine, used as constituents of beer, are to be regarded as deleterious. The question was answered in the affirmative in regard to salicylic acid and in the negative in regard to glycerine. This agent, it was stated, besides being wholly innocuous, was often formed in the digestive tract—in small quantities to be sure—during fermentative processes, as a by-product of alcohol and carbonic acid. The laxative properties of glycerine, besides, render it really a beneficial constituent of beer.

Last week a monument was erected to the memory of Prof. Bardeleben, the Nestor of German surgery, in the home of his useful and untiring labor, viz., the Charité.

The death of Prof. Jacobsohn, the famous oculist of Königsberg, has awakened deep sympathy, not only in the medical profession but also among the laity. His skill and unselfishness were both unrivaled. The best portion of his life was spent in attending to the eyes of the poor people of Eastern Prussia. He was a pupil of Graefe and worked very hard for the separation of ophthalmology from general internal medicine and for its promotion to the rank of a special science. After a fight of twenty-five years, he succeeded at last in forcing the government to erect the first special eye-clinic in Prussia, viz., at the University of Königsberg.

PERISCOPE.

Intussusception Treated by Inflation.

In the *Lancet*, Nov. 30, 1889, Dr. David W. Finlay, Physician to the Middlesex Hospital, reports an interesting case of intussusception successfully treated by inflation of air. Another under the care of Dr. Cheadle was published in the *Lancet*, Jan. 20, 1889, and reference is made in connection with it to cases previously occurring in the Hospital for Sick Children, Great Ormond street.

Dr. Finlay's patient was a boy 8 years old admitted into the Middlesex Hospital about 1 P. M. Oct. 4, 1887, with the following history: At half-past eight the same morning he suddenly complained of pain in the abdomen, almost immediately after which he went to stool, straining much, but did not pass anything. He was able to take a little breakfast, but vomited it. Before noon he had been to stool two or three times, and on the last occasion it was noticed that he had passed blood. On admission he was found to be suffering from tenesmus, and his bowels were frequently moved, a small quantity of blood and mucus being voided on each occasion. He suffered pain only just before the bowels acted, and at the same time he was attacked by vomiting and retching. The abdomen was not distended, but the left side was slightly fuller than the right. On palpation the muscles of the left side were rigid, and there was some dulness on percussion from below the left hypochondrium to the iliac crest. A sausage-shaped swelling could be felt extending from about the level of the umbilicus in an oblique direction from without inwards down to the left iliac fossa. The diagnosis being perfectly clear, it was at once decided to try the effect of inflation, and at 2.30 P. M. chloroform was administered and the operation performed with a small pair of ordinary bellows, the nozzle being covered with an india rubber tube, which was passed for two or three inches into the rectum. Previously to this the opportunity was taken of making a digital examination of the bowel, in which,

however, nothing abnormal was discovered. Under the anæsthetic the tumor in the left iliac region was much more distinctly felt. The abdomen was somewhat, but not greatly, distended by the inflation, and after two or three minutes it was found that the swelling had disappeared. The tube was then withdrawn and the boy was left at rest, a mixture containing three minims of tincture of opium and five minims of spirit of chloroform being ordered to be taken every three hours. During the following night he had several attacks of vomiting, and lay with his legs drawn up. As he had passed no urine since admission, it was drawn off by catheter; to the extent of only two ounces, however. It was very acid, sp. gr. 1.045, and deposited an abundant sediment of white lithates, being otherwise normal. He had slept for about five hours and a half during the night, and the sickness referred to came on only after drinking. The next day (Oct. 5) he was found to have no abdominal tenderness or swelling, and since the inflation he had passed no more blood, or indeed anything. He was fed with two teaspoonfuls only of liquid nourishment at a time, but vomited even that. He was accordingly ordered an effervescing mixture, with tincture of opium and hydrocyanic acid, a sinapism to the epigastrium, and half a teaspoonful of meat juice in cold water occasionally. After this there was no more sickness, and he was allowed to return gradually to ordinary diet. A note made on the seventh day after admission (Oct. 10) was to the effect that he continued to improve; there was no swelling or tenderness in the abdomen, which was soft and normally resonant. The tongue was clean and moist, but the bowels had not yet been opened. Two days later he was allowed to get up. On Oct. 17 he passed a few small masses of feces almost black in color, and by the end of the month the motions were normal and recovery complete. The temperature was practically normal throughout the whole progress of the case.

The lessons to be learnt from the foregoing case, Dr. Finlay says, are tolerably obvious and simple, but it is only by systematically recording individual experiences that a sufficient body of material is to be obtained for general use. First in importance, as contributing to the favorable result, must be set down the early period at which the case came under treatment; for although cure has followed inflation in cases of several days' standing, a favorable result in these can hardly be expected. At the same time it may be said that there are few cases in which, whatever the length of time the intussusception has existed, the effect of inflation should not be tried before recourse is had to the serious step of abdominal section. Even where the latter may be reckoned to hold out the fairest promise of success the patient when anæsthetized should be given the chance of benefit from inflation, as this, if carefully carried out, need not increase the ultimate risk of the more serious operation which may follow. Most surgical authorities recommend early laparotomy, so-called; and it is just in the early cases that the necessity for this may be obviated by inflation. Another point is that the administration of some anæsthetic is to be strongly recommended. The advantages which it affords both in clinching the diagnosis and in the satisfactory carrying out of the treatment are so obvious as to require no argument. Finally, the simplicity of the apparatus required is worthy of consideration, a pair of bellows or an injection syringe, being all that is needed.

Treatment of Hemorrhage after Extraction of Teeth.

Mr. Pillin, in a recent issue of the Journal of the British Dental Association, relates five cases occurring in his practice of secondary hemorrhage following tooth extraction. Three of the patients were members of the same family, but it is not mentioned whether there was any history of hemorrhagic diathesis. The cases are interesting on account of the length of time elapsing between the operation and the hemorrhage. The first, a man aged twenty-eight, had profuse bleeding commencing on the fifth day; a brother, aged thirty-one, notwithstanding the sockets were plugged immediately after the extraction, on the eighth; and a sister, twenty-five years of age, also on the eighth day. Of the two other cases hemorrhage occurred on the third and fifth days respectively. The treatment adopted successfully was plugging the sockets with cotton-wool saturated with tincture of perchloride of iron, and adapting over this a plate made of Stent's composition, lined with a mixture of tannin and gum tragacanth. Stent's composition is a preparation used by dentists for taking models of the mouth. It is harder than wax at the temperature of the body, and not so

flexible as gutta-percha, and therefore makes an accurately fitting and easily applied plug, and can be readily retained in position by keeping the jaws in contact by an ordinary four-tailed bandage.—*Lancet*, Nov. 30, 1889.

Removal of Renal Calculi by Toxic Doses of Belladonna.

In the *Prov. Med. Jour.*, October, 1889, Dr. Murray states that, in his experience, belladonna is more beneficial than opium in relieving the pain of renal colic. In cases of renal colic, moreover, the author contends that if the drug is pushed sufficiently long, and in large enough doses, the entire removal of the calculus—first from the pelvis of the kidney to the bladder, and then from the bladder *per urethram*—often follows. Some cases are quoted illustrating this assertion. One patient had suffered for several months from repeated attacks of renal colic, during the last of which he was seen by the author, who gave belladonna until its physiological action on the eye and throat was evident, and then it was pushed further, so that in a few hours a lithic acid calculus was passed as large as an almond. In another case a youth suffered so severely from renal pain that it was decided to operate, but, before consenting, the parents consulted Dr. Murray; he ordered twenty drops of tincture of belladonna every hour, and at the end of five hours a round rough calculus was passed. The special point to be remembered in these cases is to push the drug to its toxical stage, and keep up its action after the pain has been relieved, until a fair time has been allowed for the expulsion of the stone. You may begin with forty minims of the tincture, and repeat it every two hours, increasing or diminishing the dose according to its effect on the pain. —*London Med. Recorder*, Nov. 20, 1889.

New Method of Transplantation of the Cornea.

Dr. A. v. Hippel, in the *Archiv für Ophthalmologie*, vol. xxxiv, p. 108, has proposed that in the well-known operation for transplantation of the cornea, whilst the entire thickness of the cornea of the rabbit from which the membrane is taken, should be removed by the trephine, only the substance of the cornea should be taken away in the patient, the membrane of Descemet being carefully left uninjured. By pursuing this method he claims to have enabled a patient who was only able before the operation to count the fingers at six feet, to read $\frac{20}{200}$; whilst in a second case the patient was enabled to count the fingers at twelve feet. He considers the operation to be inappropriate for cases of ectatic leucoma, and for all cases of leucoma with complete adherence of the iris; but it is not contraindicated in cases of partial adherent leucoma, even when the opacity is of large size.—*Practitioner*, Nov., 1889.

Drainage of Wounds.

Dr. I. Boeckel, of Strassburg, who for many years had protested against prolonged drainage in the treatment of wounds, has recently discarded drainage altogether after operations, and now regards this practice as erroneous and absurd. In favor of this opinion, a report was made in May to the Société de Chirurgie, of Paris, of thirty-six cases of operation treated in the Strassburg clinic with complete and speedy success without the use of drain tubes. This list of cases included one of trephining for compound fracture of the cranium, four of cancer of the breast, two of amputation of the thigh, and ten of resection of the knee. In most instances the wound was covered by iodoform dressing, which was allowed to remain until the completion of the healing processes. Dr. Boeckel is a firm believer in the antiseptic method, but endeavors to attain simplicity of detail in the use, during and after operation, of surgical appliances and dressings. The essential point, he holds, is to maintain a rigorous antisepsis during the operation, from the first application of the knife to the completion of the dressing. In certain operations, such as resections of the knee and elbow, and, indeed, articular and osseous resection in general, Dr. Boeckel, in order to save time and to avoid all possible risk of infection from the presence of ligatures and the temporary contact of hemostatic forceps, trusts to methodical compression and vertical elevation of the limb for the prevention of hemorrhage. The surgeon, it is held, should, in the course of a long operation, wash his hands frequently in a weak solution of corrosive sublimate. Gauze pads are

used in the place of sponges, and in order to obliterate as far as possible any cavities at the bottom of the wound, the flaps are brought together by deep sutures. Owing to these precautions, Dr. Boeckel is now able in any serious operation to dispense with the inconvenient plan of drainage, and at the same time to effect complete healing of the wound under a single dressing. In all the thirty-three cases mentioned in this report, repair, it is stated, took place in a very striking manner, and without fever, pain or suppuration.—*London Med. Recorder*, Nov. 20, 1889.

Collapse in Typhoid.

Collapse in typhoid fever, due to heart failure, demands prompt attention. Among remedies alcoholic stimulants are of the greatest service. Digitalis, strophanthus, sparteine, caffeine, camphor, nitro-glycerine, and musk are useful adjuncts.

Dr. W. Maddren, in the *Brooklyn Med. Journal*, Dec., 1889, says that for combating a sudden danger from weakness of heart, Siberian musk in large doses is considered by several authorities to be a most efficient remedy. A subcutaneous injection of caffeine is superior to ether, as it is less painful, and more stimulating to the heart. The following formula for hypodermic injection is recommended by Tanret and Dujardin-Beaumetz:

℞ Caffeine . . . . . 6 grains
Salicylate of sodium . . . . . 4½ "
Distilled water . . . . . up to 16 minims

Dissolve with the aid of heat. Sixteen minims of the solution contain six grains of caffeine.

Strong tea or coffee will produce a powerful temporary effect. When the indications call for a stimulating effect for a longer time, camphorated oil should be administered hypodermically—one part camphor, five parts olive or almond oil, two to five syringefuls at a time. In using this remedy be careful to vary the place of introduction, and use no violence, or there may be a slough of the skin.

Ichthyol Collodion in Erysipelas.

The local application of a coating of ichthyol collodion, prepared according to Dr. Unna's formula, is reported to be one of the most efficient means of subduing the intumescence and of cutting short the course of erysipelas in conjunction with proper internal remedies. The formula of Unna's ichthyol collodion is as follows:

℞ Icthyol,
Ether . . . . . āā ʒ 5
Collodion . . . . . ʒ 10

—*New York Med. Times*, Dec., 1889.

Antisepsis in Typhoid Fever.

The so-called antiseptic treatment of typhoid fever is a valuable addition to the therapeutics of this disease. Dr. John A. McCockle, in the *Brooklyn Med. Journal*, Dec., 1889, says that it is well to begin antisepsis at the mouth by strict cleanliness and antiseptic washes. Carbolic acid is a deserving remedy, and one in which he has much confidence.

℞ Acidi carbol. . . . . ♏ xxiv
Glycerin. . . . . fʒii
Liquid pepsin. aromati. . . . . fʒi
Aquæ menth. pip. . . . . fʒii

M. Sig. A teaspoonful one hour after food.

This combination aids digestion, checks decomposition, and acts as a disinfectant.

Chloralamid.

The new hypnotic, chloralamid, may be administered either pure or in suspension. In the first case it should be given in a wafer or capsule or mixed with a confection. Dr. Alfred S. Gubb, in the *London Med. Recorder*, Nov. 20, 1889, gives the following formula for the administration of chloralamid in suspension:

℞ Chloralamid . . . . . gr. xxx–xl
Acid. hydrochlor. dil. . . . . ♏ ij
Syrup. Rubi Idæi . . . . . fʒiij
Aquæ dest . . . . . fʒij

M. Sig. For one dose.

The drug may also be administered per rectum as follows:

℞ Chloralamid . . . . . gr. xxx–xl
Acid hydrochlor. dil. . . . . ♏ ij
Cognac . . . . . ♏ xvj
Aquæ dest. . . . . fʒiij

M. Sig. For one enema.

Incisions into Soft Parts in Difficult Labor.

A bold operation is proposed by Dührssen in the *Prager medicinische Wochenschrift*, which he professes to have performed ten times. In each case the mother was saved, but all the children had died during the prolonged labor. Two of the mothers were in danger from eclampsia at the time of the operation. It is said to be indicated in old primiparæ where there is great rigidity of the parts with weak pains, when there is danger from eclampsia, after premature rupture of the membranes, when the pelvis is flattened so that the head of the child will not engage in the superior strait, and when the cervix is rigid or cicatricial as a result of venereal disease, carcinoma, ulceration, or operation. The technique is as follows: No speculum is required. The cervix is seized with the fingers or with forceps, and when the tissues are well stretched an incision over an inch deep is made towards the tuber ischii on each side, extending one and one-half inches up the vagina. The child is then easily removed. The hemorrhage is slight and easily controlled. After the birth of the child the wounds are drained and treated with iodoform. In cases of eclampsia an anæsthetic is not necessary. The chief danger seems at first to be that of the wounds being torn to a greater depth, but Dührrssen asserts that there is no danger of this, inasmuch as the canal thus formed is sufficiently large to allow of the passage of the child's head without causing sufficient tension to tear the wounds any deeper.— *New York Med. Journal*, Dec. 7, 1889.

Antifebrin in Quinsy.

In the *Wiener Medizinische Blätter* for August 8, 1889, Dr. W. Sahli writes that on the second day of a violent attack of quinsy he took seven grains of antifebrin, and within a quarter of an hour all headache and pain on swallowing or in mastication had completely disappeared. On the next day there was a slight return of pain, which was again almost immediately subdued by the repetition of the dose of antifebrin, and this treatment was continued on each reappearance of pain with the same results, until the disease had run its course.

Dr. Sahli refers to twelve cases of quinsy in which 4 grain doses of antifebrin likewise produced satisfactory results. The same effect was also observed by the writer in the relief of pain in angina of an epidemic of scarlet fever and diphtheria. The drug relieves pain in all movements of the throat, and, by rendering the operation painless, is a great assistance to gargling the throat, especially in children, while, of course, it also assists in the administration of food.

Dr. Sahli does not, however, claim that antifebrin is a specific for angina or diphtheria, since the pathological processes are not influenced by its administration. He administers it shaken up in a little spirits and syrup. — *Therapeutic Gazette*, Nov., 1889.

Diabetes Mellitus.

To sweeten the food of diabetics add as much as will lie on the point of a knife of the following formula :

℞ Saccharini . . . . . gr. lxxvij
Sodæ bicarb. . . . . gr. xxxj
M.

Local Anæsthesia with Seltzer Water.

Dr. Voituriez (*Journ. de sci. méd. de Lille*) recommends the use of siphons of seltzer water for this purpose, the jet being held at about four inches from the region to be anæsthetized. He uses at first two or three bottles of seltzer, which causes an anæsthesia that will last for four or five minutes, after which a small additional quantity will suffice to prolong the effect.— *American Journal of Pharmacy*, Dec., 1889.

Deodorized Iodoform Ointment.

The following deodorized iodoform ointment is quoted from the *Gazetta Med. di Torini :*

℞ Powdered iodoform . . . . . 48 grains
Powdered roasted coffee . . . . . 48 grains
Vaseline . . . . . 1 ounce
Mix.

—There is some talk of establishing a Pasteur Institute at Cambridge. It is estimated that the expenses for the first year would not exceed £700. It certainly seems absurd, says *The London Med. Recorder*, October 21, that England, which furnished so large a quota of patients for M. Pasteur, should not have an inoculation station within its own shores.

THE
MEDICAL AND SURGICAL
REPORTER.

ISSUED EVERY SATURDAY.

CHARLES W. DULLES, M.D.,
EDITOR AND PUBLISHER.

N. E. Cor. 13th and Walnut Streets,
P. O. Box 843. Philadelphia, Pa.

☞ SUGGESTIONS TO SUBSCRIBERS:
See that your address-label gives the date to which your subscription is paid.
In requesting a change of address, give the old address as well as the new one.
If your REPORTER does not reach you promptly and regularly, notify the publisher *at once*, so that the cause may be discovered and corrected.

☞ SUGGESTIONS TO CONTRIBUTORS AND CORRESPONDENTS:
Write in ink.
Write on one side of paper only.
Write on paper of the size usually used for letters.
Make as few paragraphs as possible. Punctuate carefully. Do not abbreviate or omit words like "the" and "a," or "an."
Make communications as short as possible.
NEVER ROLL A MANUSCRIPT! Try to get an envelope or wrapper which will fit it.
When it is desired to call our attention to something in a newspaper, mark the passage boldly with a colored pencil, and write on the wrapper "Marked copy." Unless this is done, newspapers are not looked at.
The Editor will be glad to get medical news, but it is important that brevity and actual interest shall characterize communications intended for publication.

THE END OF THE YEAR.

With the conclusion of another year and of the sixty-first volume of the REPORTER, the Editor extends to its readers his best wishes for their prosperity and happiness, and his thanks for the evidence they have given of their sympathy with principles which have guided him in conducting it.

We trust that the readers of the REPORTER will have observed steady improvement in the character of the original articles, and the development of the departments of clinical lectures and hospital reports, as well as of foreign correspondence.

In the Editorial department the greatest care has been exercised to present our readers with entirely fresh abstracts and translations every week and to have the book reviews honest and fair and wholly in the interest of our readers. In the Editorials themselves we have presented, as the Index shows, a very wide variety of subjects, some of them of the highest degree of importance, and all of interest.

In looking back over the year just ending it will be seen that on more occasions than one it has seemed proper to pass beyond the range of mere scientific discussion, and to comment on men and measures connected with our profession. In this the Editor has endeavored at all times to voice the sentiment of the best part of the profession, of that part which hates and despises sham and clap-trap, and which regards integrity as indispensable to professional character. This part of his duty the Editor of the REPORTER will endeavor to discharge according to his best judgment, remembering that the REPORTER is published not for any one locality or any set in the profession, but for the whole of this continent and parts of almost every other one. At the same time he will receive with appreciation any suggestions from its many readers, looking to an improvement in the REPORTER, and will be very glad to have their expressed support in any moral question which it may discuss.

DEVELOPMENT OF PULMONARY PHTHISIS.

At the meeting of the American Public Health Association held last October, Dr. P. H. Kretschmar, of Brooklyn, read a paper on the Prevention of Pulmonary Consumption, in which he said that he had no doubt that the disease could be spread by contagion, and propounded some interesting statements in regard to its predisposing causes. He said if there are many children in a family, those born after the sixth or seventh are apt to develop consumption; if the children in a large family are born at short intervals, the younger ones are apt to develop consumption; and, if the offspring of healthy parents, born under the conditions named above, escape the disease, their children are prone to develop it. Dr.

Kretschmar confessed that these views were novel, but said that he thought they were fully justified by his own experience and that of other physicians who had recorded their observations.

It is likely that the observation of any careful student of hereditary influences would be found to confirm the opinions of Dr. Kretschmar; but we must confess our inability to see how this view can be harmonized with his belief in the contagious theory of phthisis. As we understand it, a contagious disease is one that is entirely untrammeled in its choice of victims, except in the case of those who are protected against its invasion. This is clearly the case with small-pox, which is a typical contagious disease. If this disease would, for instance, attack those who happened to be born in the latter part of the reproductive period, in preference to those who are born in the middle portion of this period, it would be conclusive evidence that some special vulnerability to the disease, not apparent to the senses, existed in such individuals, and that the germ of small-pox is not free to act, and not the only factor; yet it is a well-established clinical fact that small-pox respects none but those who are specially protected by a modified form of its own virus.

In addition to this, there seems to be another incongruity in the contagious theory of phthisis in so far as its behavior is related to that of contagious diseases. It has been stated that small-pox protects against a second attack, and it is also true that the offspring of those who have had the disease are less liable to it than others, showing that a certain degree of immunity is conveyed by inheritance. Now in regard to phthisis the very opposite holds true. This disease does not only not afford protection against, but actually paves the way for a second attack, if the individual is fortunate enough to live through the first; while at the same time it increases the vulnerability of his descendants to the disease.

It is very true that much has been done in the laboratory to show that phthisis is an inoculable disease, but that which is gleaned from this source must not clash with the solid facts which are gleaned from the field of practical experience; for under these circumstances the former, instead of serving as a beacon light to the searcher after truth, will "hold eternal anarchy, and by confusion stand."

A BAD BLUNDER.

In view of the opinions expressed in our Editorial, December 21, on "Physicians and Politicians," it will not surprise the readers of the REPORTER that we note with great regret the fact that the Faculty of the Jefferson Medical College last week joined hands with an institution for which it has heretofore expressed the greatest contempt, in trying to secure some advantage from the shameful interference of the Mayor in the personnel of the Medical Staff of the Philadelphia Hospital.

To the discomforts which are supposed to come with such strange bed-fellowship, there has been added the open reproof of the most ably-conducted newspapers in Philadelphia, which have criticised not only the action of the Jefferson Medical College, but also the grounds upon which this was taken. They have espoused the transparent fallacy of the assumption that the medical schools of Philadelphia have a right to "representation" in the Staff of the Municipal Hospital, and the hollow selfishness of the demand—first put forward by the Medico-Chirurgical College—that the medical men under whose direction the most remarkable improvements have been effected at the Philadelphia Hospital shall be turned out to make room for others whose strongest claim is that this school has not what it thinks is its share of the offices.

These criticisms will probably suffice to convince the Faculty of the Jefferson Medical College that they have committed a serious blunder, regarded merely from the

standpoint of general morality; but their adoption of the methods of politicians and abandonment of ethical principles of the the profession call for condemnation also from independent medical journals. It is not pleasant to have to speak thus, but it seems to be a duty, and it must be done.

We trust that this will be the last time we shall have to express disapproval where praise would be a more pleasant task; but if necessary the REPORTER will return to a consideration of the crisis at the Philadelphia Hospital, and will not shrink from expressing such opinions as may seem to be in accordance with the principles of right, and conducive to the honor and dignity of the medical profession.

NOTES AND COMMENTS.

Falsification of Wine in Brazil.

It appears, from a small pamphlet referred to in the *Lancet*, Nov. 23, 1889, by Dr. Campos da Paz, of Rio de Janeiro, that the manufacture of imitations of wines and liqueurs flourishes unchecked in Rio and forms a more or less important industry. The replies, based on analyses, which were returned by the local official chemists to inquiries submitted by Dr. Campos da Paz and Dr. Freire show that extensive and systematic falsification of a kind likely to be seriously injurious to public health is practiced. Indigo-carmine, dinitro-cresylate of potassium, aloes, chloroform, and the compound ethers of valeric, butyric, and caproic acid, oxalic acid, and amyl alcohol are among the ingredients used in this branch of misapplied chemistry.

Polluted Rivers.

At the meeting of the Public Health Association, held recently in Brooklyn, Dr. L. S. Kilvington, of Minneapolis, then presented a paper on "Statistics of River Pollution," with some observations relating to the destruction of garbage and refuse matter, and said that the majority of health officials in this country favor the cremation system. He also stated, that in the Mississippi river, during the past year, eight cities alone deposited 152,675 tons of garbage and offal, 108,250 tons of night-soil, and 3,765 dead animals. In the Ohio river, five cities, in the same period, dumped 46,700 tons of garbage, 21,157 tons of night-soil, and 5,100 dead animals. In the Missouri river, four cities cast 36,000 tons of garbage, 22,400 tons of night-soil, and 31,600 dead animals. No theory of self-purification of running water will dwarf the magnitude of this sanitary crime. The speaker doubted the practicability of using garbage as a fertilizer, because, while it contained fertilizing elements, they were not sufficiently concentrated for agricultural use.

Mercurial Flannel.

In the October number of *L'Union Pharmaceutique*, M. P. Carles gives a detailed account of the method of preparing mercurial flannel, an article which appears to be coming into use in France. Its introduction is due to Professor Merget, of Bordeaux, who in his recent thesis for the degree of Doctor of Medicine, referred to in the *British Med. Journal*, Nov. 23, 1889, shows that when frictions are made with mercurial ointment, the mercury is not absorbed by the healthy skin, and that the metal acts only by the vapors which it spreads, and which are introduced into the system by means of the respiratory passages. The inconveniences attending the use of mercurial applications are well known; they are sometimes difficult to apply, and occasionally they cause cutaneous eruptions and salivation. Professor Merget has proposed to replace them by applications of thick tissues, upon which is fixed an adherent deposit of mercury reduced mechanically to an impalpable powder, and placed in conditions most suitable for it to become slowly vaporized. Flannel is the material used for this purpose. It is first treated with a solution of sodium carbonate in order to free it from grease, and thus prepared it is dipped into a saturated solution of mercurous nitrate and afterwards into liquor ammoniæ; this solution precipitates the mercury in the tissues of the flannel as mercurous ammonium. To make use of the mercurial flannel it is sufficient to place a square of 25 centimetres on one side near the respiratory passages. Although the system is thus in direct contact with the mercurial vapors, it is not saturated by them, for they are rapidly eliminated by the renal and intestinal excretions, and thus an equilibrium is maintained. Experience has

shown that respiring these vapors every night, and leaving them off during the day, sick people and those in good health support them without the least inconvenience during several months. It is necessary to observe that if the mercurial dust from the flannel be inhaled with the vapors, salivation is rapidly produced. The piece of flannel, therefore, must be enclosed in a bag of some light tissue, so as to prevent the dusting out of the mercurial powder. The flannel thus protected is placed under the patient's head if he sleeps on his side, or upon his chest if he lies upon his back. This mercurial flannel will give sensible vapors of mercury which can be recognized by tests for years. It weakens, however, sensibly every day when in contact with the hot body; it is therefore necessary to renew it about every three weeks. It can also be used as an application to the skin in cutaneous affections due to parasites. For this purpose it is applied in the form of a glove, a sleeve, or bandage.

Catarrh of Pharynx.

The following is claimed to be a useful gargle in catarrh of the pharynx:

NEWS.

—Dr. S. H. Nichols, Surgeon of the Bloomingdale Insane Asylum, New York, died Dec. 17.

—The Harvard Dental School recently received a gift of $1,000 to be added to its endowment fund.

—The St. Louis Post-graduate School of Medicine have sold their interests in the *St. Louis Polyclinic* to Dr. L. A. Turnbull, the present Editor.

—Dr. Thomas B. Harvey, of Indianapolis, dean of the faculty of the Indiana Medical College, died on Thursday, the 5th inst., within a few hours after an attack of apoplexy that overwhelmed him while he was delivering a lecture to his class.

—The *British Medical Journal* states that Professor Virchow continues to work diligently upon the new edition of his work on "Cellular Pathology," and that he expects to have it completed by the time that the International Congress meets at Berlin.

—A Medical College for Chinese has been recently established at Hong Kong and is evidently doing good work in instructing the native students in medicine. It is in charge of Mr. Cantlie, F. R. C. S., late of Charing-cross Hospital as Dean, and there is a full staff of English lecturers and about thirty students.

—Latest advices from St. Petersburg are to the effect that cholera is dying out in the provinces of Persia. In Southern Mesopotamia, on the other hand, all over Irak and among the nomads of the Syrian desert, who resist all medical superintendence, the epidemic is raging with great violence. The Persian authorities are executing the quarantine regulations with considerable rigor.

—So many exaggerated and misleading stories have been sent out in reference to typhoid fever at Yale University, that the faculty, on December 13, had all of the buildings examined by a sanitary engineer, who reported that the buildings and their sanitary systems were in first-class condition, and that the sickness could not have been caused by unsanitary conditions of the dormitories.

—Dr. Seth Pancoast died at his residence in Philadelphia, on the morning of Dec. 16. Dr. Pancoast was born in 1823; was graduated in Medicine at the University of Pennsylvania in 1852. In 1858 he became Professor of Anatomy in the Philadelphia Women's Medical College, which position he held for five years. He had since been made Professor Emeritus and continued such until 1882.

—The coroner's jury in the case of Harris, the New York salesman, who was killed by an electric light wire coming in contact with a show-case which he was assisting in carrying, has rendered a verdict which finds the Brush Electric Light Company wholly responsible for Harris's death. The finding also makes the following recommendations: (1) That the Board of Electrical Control and the Board of Health be requested to use extraordinary and speedy measures to have the wires of all the electric light companies of the city laid underground, and, (2) that the said Boards use all necessary care to have the wires and lamps of all the electric light companies properly insulated.

BUFFALO LITHIA WATER

IN THE TREATMENT OF CHRONIC GASTRIC CATARRH

CLINICAL REPORTS.

CHRONIC GASTRIC CATARRH AND URIC ACID CALCULI.

A case stated by Dr. JNO. C. COLEMAN, of Scottsburg, Va., a retired Surgeon of the U. S. Navy.

"Mr. C. was for a number of years a sufferer from **CHRONIC GASTRIC CATARRH.** While his diet *was exclusively* **TEA** and **CRACKERS, BREAD** and **MILK,** *and other similar articles,* it was frequently thrown off in an undigested state soon after taking it, and at times he discharged from an empty stomach a strongly acid glairy mucus. A marked **URIC ACID DIATHESIS** supervened, consequent upon which he suffered for a period of some two years great **VESICAL IRRITATION** and possible **CYSTITIS,** attended by pain so intense and constantly present, as to require that he should be kept for the most part under the influence of opiates. After a persistent, but ineffectual exhibition of all remedies supposed to be indicated in the case, he was put for the latter affection upon the **BUFFALO LITHIA WATER,** Spring No. 2, with the happiest possible effect.

"In a few weeks, after commencing the use of it, the irritable condition of the *Bladder* was so far relieved that he was enabled to dispense entirely with the use of opiates. At the expiration of some eight weeks he had an attack of unusual severity, from which he was relieved by the discharge of a **CALCULUS,** followed at short intervals by the discharge of three others, which proved to be the termination of this trouble, as from that time there was entire subsidence of the painful symptoms described, and the *Bladder* resumed its natural state.

"While prescribed with special reference to the relief of the *Irritable Bladder,* the action of the water was not less surprisingly happy in the **GASTRIC AFFECTION,** with remarkable promptness correcting the highly acid condition of the **STOMACH,** restoring a healthy digestion and assimilation, and *tone* and *vigor* to the depressed *Nervous System.*

"In a few months he was able to eat, with perfect impunity, the coarsest articles of diet. He is now, after a lapse of several years, in robust health, having had no return of these painful maladies."

CHRONIC GASTRIC CATARRH.

Case of JOHN P. KEELING, Esq., stated by Dr. S. S. KEELING, Norfolk, Va., Member Medical Society of Virginia.

"Mr. John P. Keeling labored under **CHRONIC DYSPEPSIA,** and was always subject to attacks of *Spasmodic Gastralgia* immediately upon taking food into the stomach, which attacks were not at all amenable to treatment. Not unfrequently the stomach *rejected everything in the way of food and drink,* and he was of necessity confined to the lightest possible articles of diet, *meat and vegetables being entirely excluded.* He became so prostrated that it was with difficulty he could walk across his chamber floor, and had often to be lifted about. Such was the state of his **NERVOUS SYSTEM** *that great solicitude was felt as to his mental condition.*

"He visited Baltimore for medical aid, and was for many months under the treatment of some of the most eminent men of the profession in that city, but without beneficial result, and was finally advised that he had nothing to hope from remedies.

"Returning in an extremely critical condition to his home in the county of Princess Anne, he came under my professional care. Satisfied that medicine was unavailing in the case, I advised the **BUFFALO LITHIA WATER,** Spring No. 2. His stomach, however, was in a highly irritable condition, and I found it necessary to administer it in very small quantities; and it was at first given not exceeding an ounce at a dose, repeated at stated intervals. At the expiration of the third day the irritability of the stomach was decidedly less, and the quantity was then increased from day to day until the thirteenth day, when I found that the patient could take twelve ounces, which I regard as maximum dose at any time. Persisting in its use, on the twenty-eighth day he was free from pain, the stomach in a normal condition readily receiving both solids and liquids in moderate quantities, strength greatly increased, and nervous symptoms entirely relieved. At the expiration of the seventh week he was able to attend actively and regularly to his business on the farm. His recovery, which I regard as one of the most remarkable I ever knew of, I attribute entirely to the **BUFFALO LITHIA WATER."**

GASTRO-INTESTINAL CATARRH.

Case of Mrs. Dr. F. J. GREGORY, of Virginia, reported by F. J. GREGORY, M.D., Keysville, Va.

"For eighteen months my wife, aged forty-one years, was a sufferer from a **GASTRO-INTESTINAL CATARRH,** which resisted my best-directed efforts at relief. The taking of the smallest quantity of the most easily-digested food on the stomach would produce an attack of *nausea and vomiting, the severity of which is seldom witnessed,* and when the stomach was free of food she would have attacks of *Gastralgia of the most excruciating nature.* She also suffered from habitual constipation, and at times with hemorrhages from the bowels. I pursued the usual line of treatment, such as simple bitters, Dilute Hydrocyanic Acid, Bismuth, etc., and called to my help two of the most skilled physicians in Southside Virginia, who supplemented my treatment with some of the newer drugs, such as **EFFERVESCING BICARB. POTASS. LACTOPEPTINE, CARLSBAD MINERAL SALTS,** etc., but with no benefit, and so her condition went on from bad to worse *until death seemed almost imminent from inanition.* I then put her on a milk diet with a glass of **BUFFALO LITHIA WATER,** Spring No. 2, every hour or so during the day, and *after the use of the first bottle improvement was marked, and before a case of it was used I regarded her cure as complete.* It has been nearly two years since, and there has been only one slight recurrence, which was a few days since, and it readily disappeared on the use of the water for a few days."

Water in cases of one dozen half-gallon bottles, $5 per case, at the Springs.

THOMAS F. GOODE, Proprietor,

BUFFALO LITHIA SPRINGS, VIRGINIA.

THE NEW HYPNOTIC
SULFONAL-BAYER.

SULFONAL was discovered by Prof. Eugen A. Baumann, of Freiburg University, and was first prepared by the Farbenfabriken vorm. Friedr. Bayer & Co., Elberfeld.

SULFONAL (Diæthylsulfondimethylmethan) is in the form of colorless prisms, odorless, and tasteless, melting at 125.5° C. (258° F.) and has the composition $(C H_3)_2=C=(C_2 H_5 SO_2)_2$. It is slightly soluble in cold water, but easily soluble in hot water or alcohol.

SULFONAL was first examined as to its physiological and pathological effects by Prof. A. Kast, of Freiburg University, and its hypnotic action was discovered and studied by him.

Since then SULFONAL has been the subject of numerous trials and experiments by many eminent and experienced physicians. Their testimony is unanimously favorable, and the conclusions reached by them are as follows:

SULFONAL is a prompt and reliable hypnotic, which in proper doses, produces quiet, natural sleep, lasting a number of hours.

SULFONAL has no unfavorable effects on the heart and the circulation, nor on the temperature, the pulse, or the respiration.

SULFONAL produces no disagreeable secondary symptoms; the patients with very few exceptions awake from their sleep feeling strong and greatly refreshed.

SULFONAL does not interfere with the process of digestion.

SULFONAL is a hypnotic, and not a narcotic; it acts by giving rest to the cells of the cerebral cortex, thereby causing sleep.

SULFONAL does not create an unconquerable desire for its repeated use; there is no danger of a SULFONAL-habit. Neither is it necessary to increase the dose after long-continued use.

SULFONAL is best administered at supper-time, dissolved in hot liquids, *e. g.*, a bowl of soup or broth, a cup of milk, tea, coffee, cocoa, etc.

These points will be found to be fully exhibited in the series of contributions contained in our pamphlet, which will be mailed on application.

SULFONAL-BAYER is supplied by us in half-ounce and one-ounce vials.

We prepare 5-grain and 15-grain Tablets of Sulfonal-Bayer. The tablet form is admirably adapted to the purpose of administering this drug, as when they are placed in the liquids, they disintegrate and are thus received into the system.

We also put up Sulfonal-Bayer in the form of our Soluble Pills, containing five grains each.

THE NEW ANTIPYRETIC
PHENACETINE-BAYER.

Phenacetine-Bayer (Para-Acetphenetidine) is a white, glossy, crystalline powder, perfectly tasteless, melting at 135° C.=307° F and has the composition $C_6 H_4 <^{O.C_2H_5}_{NH(CO-CH_3)}$.

It is slightly soluble in water, a little more soluble in glycerine, but most freely in alcohol.

Phenacetine-Bayer was first prepared by the Farbenfabriken, formerly Friedr. Bayer & Co., Elberfeld, and is of absolute purity and uniform quality.

Summarizing the superiority of Phenacetine-Bayer over other antipyretics and antineuralgics, the following conclusions are formed:

1. ***Phenacetine-Bayer is an efficacious antipyretic.***
2. ***It does not develop any disagreeable or noxious after-effects.***
3. ***The dose required is half that of Antipyrine.***
4. ***It is perfectly tasteless.***
5. ***On account of its innocuousness and tastelessness, it is a valuable antipyretic both in adults and in children.***
6. ***Phenacetine-Bayer is an important antineuralgic; its effect is more energetic than that of Antipyrine and does not cause lassitude or any other disagreeble symptoms.***

Our pamphlet on Phenacetine-Bayer, containing the valuable testimony of eminent physicians will be mailed on application.

We offer Phenacetine-Bayer in one-ounce vials, or in the form of our Soluble Pills of the strength of two and four grains to each pill.

RABUTEAU'S DRAGEES OF IRON

Laureate of the Institute of France.—Prize in Therapeutics.

The studies made by the Physicians of the Hospitals have demonstrated that the **Genuine Dragees of Iron of Rabuteau** are superior to all other preparations of Iron in cases of *Chlorosis, Anæmia, Leucorrhœa, Debility, Exhaustion, Convalescence, Weakness of Children*, and the maladies caused by the Impoverishment and Alteration of the blood after periods of fatigue, watching, and excesses of any kind.

TAKE 4 TO 6 DRAGEES DAILY.

Rabuteau's Elixir of Iron is recommended to those persons who may be unable to swallow the Dragees. Dose —*A small wineglassful with meals.*

Rabuteau's Syrup of Iron is specially designed for children. Chalybeate medication, by means of **Rabuteau's Iron,** is the most economical and the most rational known to therapeutics.

No constipation, no diarrhœa, complete assimilation.

Take only the GENUINE IRON OF RABUTEAU of

CLIN & CO., Paris.

SOLUTION OF THE SALICYLATE OF SODA OF DOCTOR CLIN.

Laureate of the Paris Faculty of Medicine (MONTYON PRIZE).

Dr. Clin's Solution, always identical in its composition, and of an agreeable taste, permits the easy administration of *pure Salicylate of Soda*, and the variation of the dose in accordance with the indications presented.

"The *Salicylate of Soda* used by **Clin** is of perfect purity, "and is prepared with the greatest care; it is a medicament "in which we may have every confidence."

—*Paris Society of Medicine, Meeting of Feb. 8th, 1879.*

Clin's Solution, very exactly mixed, contains: 2 grammes of *Salicylate of Soda* per tablespoonful, 50 centigrammes of *Salicylate of Soda* per teaspoonful.

Paris—CLIN & CO.—Paris

CLIN & CO.,—Paris.

GRAND NATIONAL PRIZE OF 16,600 FRANCS,

QUINA-LAROCHE

This meritorious **Elixir, QUINA-LAROCHE,** is prepared from the three Cinchonas; it is an agreeable and doubtless highly efficacious remedy.

—*The Lancet.*

VINOUS ELIXIR,

A STIMULATING RESTORATIVE

—AND—

ANTI-FEBRILE TONIC.

QUINA-LAROCHE under the form of a vinous **Elixir** contains the totality of the numerous principles of the **three** Cinchona barks. It is a preparation which renders great services to Therapeutics.—Extract of the *Gazette des Hôpitaux*, Paris.

FAR SUPERIOR TO ALL ORDINARY CINCHONA WINES.

LAROCHE'S QUINA, tried by the Academy of Medicine of Paris, is a specially prepared COMPOUND EXTRACT of Quinquina, a careful analysis, confirmed by experience, has shown that most of the wines and syrups hitherto used have not contained all the properties of this precious bark, of these some, although beneficial, are altogether lost, while many preparations contain but half the properties of the bark in varying proportions.

MR. LAROCHE, by his peculiar method, has succeeded in extracting all the active principles of the quinquina, combining these with *Catalan Wine* forming an Elixir free from the disagreeable bitterness of other similar preparations. Practitioners have found triple advantages in the use of this Elixir, it is a *strong tonic*, is easily administered, and perfectly harmless, being free from the unpleasant effects of Quinine.

THE FERRUGINOUS QUINA-LAROCHE is the invigorating tonic *par excellence*, having the advantage of being easily assimilated by the gastric juice; without, in any way, deranging the action of the digestive organs, proving itself to be a most efficacious remedy in cases of impoverishment of the blood, ANÆMIA, CHLOROSIS, INTESTINAL HÆMORRHAGE, CASTRALGIA, EXHAUSTION, ETC., ETC.

BROMIDIA

THE HYPNOTIC.

FORMULA.—

Every fluid drachm contains 15 grains EACH of Pure Chloral Hydrat. and purified Brom. Pot., and one-eighth grain EACH of gen. imp. ext. Cannabis Ind. and Hyoscyam.

DOSE.—

One-half to one fluid drachm in WATER or SYRUP every hour, until sleep is produced.

INDICATIONS.—

Sleeplessness, Nervousness, Neuralgia, Headache, Convulsions, Colic, Mania, Epilepsy, Irritability, etc. In the restlessness and delirium of fevers it is absolutely invaluable.

IT DOES NOT LOCK UP THE SECRETIONS.

PAPINE

THE ANODYNE.

Papine is the Anodyne or pain-relieving principle of Opium, the Narcotic and Convulsive Elements being eliminated. It has less tendency to cause Nausea, Vomiting, Constipation, Etc.

INDICATIONS.—

Same as Opium or Morphia.

DOSE.—

(ONE FLUID DRACHM)—represents the Anodyne principle of one-eighth grain of Morphia.

IODIA

The Alterative and Uterine Tonic.

FORMULA.—

Iodia is a combination of active principles obtained from the Green Roots of Stillingia, Helonias, Saxifraga, Menispermum, and Aromatics. Each fluid drachm also contains five grains Iod. Potas., and three grains Phos. Iron.

DOSE.—

One or two fluid drachms (more or less as indicated) three times a day before meals.

INDICATIONS.—

Syphilitic, Scrofulous and Cutaneous Diseases, Dysmenorrhea, Menorrhagia, Leucorrhea, Amenorrhea, Impaired Vitality, Habitual Abortions, and General Uterine Debility.

Crystalline Phosphate

A TISSUE FOOD

PHOSPHATIC FOOD PRODUCTS TRADE MARK

Contains all essential inorganic components of the tissues in a semi-solid, easily soluble, crystalline mass,

COMPOSED OF

ACID PHOSPHATE OF CALCIUM.

WITH

Acid Phosphate of Magnesium,
" " " Iron,
" " " Sodium,
" " " Potassium,
Chloride of Potassium,
" " Sodium
Sulphate of Potassium,
and Phosphoric acid.

INDICATIONS:

STOMACH DISORDERS, such as Indigestion, Flatulence Gastric Catarrh, and Poor Appetite, Constipation, etc.

WRONGS OF NUTRITION, as in Scrofula, Rickets, Caries, Marasmus, Delayed Union of Fractures, Necrosis of Tissue, Difficult or Delayed Dentition and Development, etc.

NERVOUS AND GENERAL DEBILITY AND SLEEPLESSNESS, as from Sexual Excess, Venerial Disease, Childbearing, Nursing, Loss of Blood or other fluids, Menstrual and other Diseases of Women, abuse of Alcohol, Tobacco and Narcotics, Protracted Illness, etc.

DEBILITY AND DYSPEPSIA.—*Your preparation of* **Crystalline Phosphate,** *I have found to be very excellent in cases of Debility from Nerve Exhaustion. It is a good auxilliary in Gastric and Dyspeptic Troubles, and from my experience I regard it as a reliable preparation.* T. GRISWOLD COMSTOCK, A. M., M. D., PH. D., ST. LOUIS, MO.

LENTZ'S
NEW COMPACT
OPERATING SET
No. 10.

One Amputating Knife (Leg and Arm). One Finger Knife. One Hernia Knife. One Sharp Curved Bistoury. Two Scalpels. One Tenotome. One Tenaculum. One pair Scissors, curved or flat. One Saw, 9-inch blade. One Liston's Spring Bone Forceps. One Artery and Needle Forceps, improved. One Dressing Forceps. One Esmarch's Flat Rubber Tourniquets, with Chain. One Director, with Aneurism Needle. Two Silver Probes. Silk, Wire, Wax, and Needles.

The above instruments are put up in a fine Morocco Case with nickel trimmings, lined with velvet, and has extra space for Trephine and Elevator, if desired. With the *sixteen* instruments contained in this case, any ordinary operation may be performed.

Size, 11 in. long, 4 in. wide, 2 in. high

Price, $25. With Trephine and Handle and Trephine Elevator in addition, $29.65. We also make the above case with hard rubber antiseptic handles on knives and saw. Price, $29.00. With Trephine and Elevator in addition, $33.65.

Discount 25 pr. ct. to Physicians

Our New Catalogue of 260 pages will be sent on receipt of 10 cents for postage.

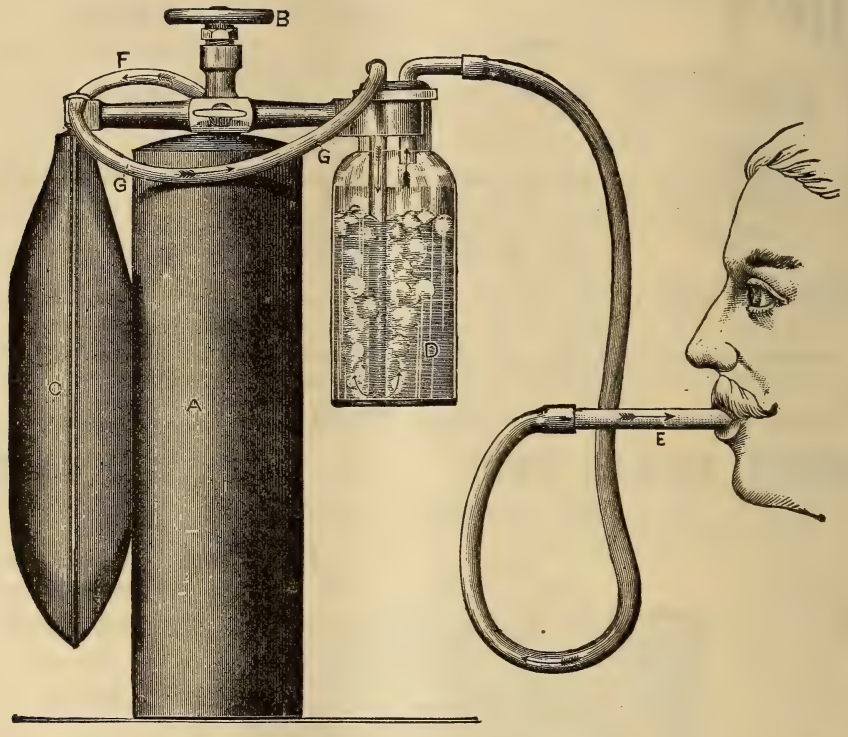
Established 1866. **Philadelphia.**

INHALATION APPARATUS

FOR

THE THERAPEUTIC ADMINISTRATION OF OXYGEN.



In the treatment of lung troubles by Oxygen its exhibition by inhalation is preferred. The apparatus herewith shown is a modification of the Nitrous Oxide apparatus which we have supplied for many years. It is made in the best manner throughout, and is the outcome of years of experience in the manufacture of gas apparatus. It will be found to meet all the requirements.

We supply the gas in two sizes of cylinders, containing respectively forty and one hundred gallons, either pure Oxygen, or a mixture of Oxygen and Nitrous Oxide in definite proportions of 20 per cent., and forty per cent. of Nitrous Oxide.

Whether pure or mixed the gas is sold at the uniform price of 5 cents a gallon. The cost of the cylinders will be refunded on their return empty with the valves in good condition. Full description of Inhalation and Enema apparatuses with directions for use accompany each apparatus, or will be supplied on application.

PRICES.

Inhalation Apparatus	$5.00
Cylinder, 40 gallons' capacity	6.00
40 gallons Gas, either pure Oxygen or mixed Oxygen and Nitrous Oxide	2.00
Complete Apparatus, Cylinder, and 40 gallons Gas	$13.00
Inhalation Apparatus	$5.00
Cylinder, 100 gallons' capacity	15.00
100 gallons Gas, either pure or mixed	5.00
Complete Apparatus, Cylinder, and 100 gallons Gas	$25.00

THE S. S. WHITE DENTAL MFG. CO.,

PHILADELPHIA, NEW YORK, BOSTON, CHICAGO, BROOKLYN.

THE BEST ANTISEPTIC
FOR BOTH INTERNAL AND EXTERNAL USE.

ANTISEPTIC, PROPHYLACTIC, DEODORANT.

LISTERINE

NON-TOXIC, NON-IRRITANT, NON-ESCHAROTIC.

FORMULA—Listerine is the essential antiseptic constituent of Thyme, Eucalyptus, Baptisia, Gaultheria and Mentha Arvensis, in combination. Each fluid drachm also contains two grains of refined and purified Benzo-boracic Acid.

DOSE—Internally: One teaspoonful three or more times a day (as indicated) either full strength, or diluted, as necessary for varied conditions.

LISTERINE is a well-proven antiseptic agent—an antizymotic—especially adapted to internal use, and to make and maintain surgical cleanliness—asepsis—in the treatment of all parts of the human body, whether by spray, irrigation, atomization, or simple local application, and therefore characterized by its particular adaptability to the field of

PREVENTIVE MEDICINE—INDIVIDUAL PROPHYLAXIS.

Diseases of the Uric Acid Diathesis.

LAMBERT'S

LITHIATED HYDRANGEA

KIDNEY ALTERATIVE—ANTI-LITHIC.

FORMULA—Each fluid drachm of "Lithiated Hydrangea" represents thirty grains of FRESH HYDRANGEA and three grains of CHEMICALLY PURE Benzo-Salicylate of Lithia. Prepared by our improved process of osmosis, it is INVARIABLY of DEFINITE and UNIFORM therapeutic strength, and hence can be depended upon in clinical practice.

DOSE—One or two teaspoonfuls four times a day (preferably between meals).

Urinary Calculus, Gout, Rheumatism, Bright's Disease, Diabetes, Cystitis, Hæmaturia Albuminuria, and Vesical irritations generally.

We have much valuable literature upon { GENERAL ANTISEPTIC TREATMENT, LITHEMIA, DIABETES, CYSTITIS, ETC. } To forward to Physicians upon request.

Geo Hamlin Prest. Chas Roome Parmele Treas.

GENTLEMEN:

The Case of your wines sent me for analysis by Dr. A. L. Hummel, of the "Annals of Hygiene," containing specimens of your La Rosa Zinfandel, Mataro, Riesling, Royal Tokay, and Royal Grape Brandy, has been duly received.

I have examined them for the common contaminants of wine; to wit: Sulphurous acid and sulphites, salicylic acid, fuchsin, lead salts, etc., none of which I found present therein.

I have also determined their alcoholic strength, extractives, and ashes, and found them to correspond strictly in this respect with the standard of pure and natural wines, which cannot be said of many of the imported wines.

As a native of a wine-producing country, I consider myself somewhat of a judge of wines, and regard your products as comparing more than favorably with most of the wines from abroad which are sold at higher prices, so much so that I enclose within my order for fifty bottles of La Rosa Zinfandel, which I expect to use hereafter exclusively at my table.

Very Respectfully,

L. WOLFF, M.D.,
Demonstrator of Chemistry, Jefferson Medical College.

McARTHUR'S SYRUP.

(SYR: HYPOPHOS: COMP: C. P. McARTHUR.)

Its use is indicated in Consumption and Tuberculosis, Diseases of the Chest, Chronic Cough, Throat Affections, General Debility, Brain Exhaustion, Impotence and Loss of Memory.

The point of primary importance in the use of the Hypophosphites is their *chemical* purity, but unfortunately they are too often adulterated.

So little seems to be generally known, even among the medical profession, with regard to the chemistry of the Hypophosphites, and the absolute necessity of CHEMICAL purity, that we call attention to this point.

One of the first effects produced by the use of our CHEMICALLY PURE Hypophosphites is a general increase of nervous energy, with a feeling of ease and comfort.

The second effect is an increase of appetite; digestion is improved, and the bowels become regular in their action, the quantity and color of the blood is increased, respiration is controlled, a better expansion of the chest is observed, cough improves, easy expectoration is produced, night perspiration diminishes, the face becomes fuller, the lips red, the nails and hair grow, and in children the teeth, showing the importance of the Hypophosphites on the organ of nutrition.

☞ Physicians when prescribing will please write thus:

℞ SYR: HYPOPHOS: COMP: McARTHUR. ONE BOTTLE.

As it is made *only for physicians* there are no printed wrappers or advertisements about the bottle.

Our pamphlet on the **CURABILITY AND TREATMENT OF CONSUMPTION,** sent free to physicians upon application.

We will send one bottle of McArthur's Syrup to any physician, without charge, who will pay the express charges on the same.

Mention this Journal. McARTHUR HYPOPHOSPHITE CO., BOSTON, MASS.

The Curd of Cow's Milk Made as Soft and Digestible as that of Woman's Milk.

"From experiments which I have recently made — and my thanks are due to Prof. Salisbury of the Woman's Medical College, for assistance — it seems that the claim which is made by the advocates of the MELLIN'S FOOD is true, and that the addition of this food to cow's milk does cause it to break up in very small, flaky curds."— *Dr. Chas. Warrington Earle, Professor of Diseases of Children, Woman's Medical College, Professor of Obstetrics, College Physicians and Surgeons, Chicago, in his paper on Infant Feeding, before the American Medical Association, May, 1888.*

Any physician having a case in which he desires to test MELLIN'S FOOD can obtain a sample sufficient for trial, free of all expense, by application.

THE BEST NATURAL APERIENT.

THE APOLLINARIS COMPANY, LIMITED, London, beg to announce that, as numerous APERIENT WATERS are offered to the public under names of which the word "Hunyadi" forms part, they have now adopted an additional Label comprising their Registered Trade Mark of selection, which consists of

A RED DIAMOND.

This Label will henceforth also serve to distinguish the HUNGARIAN APERIENT WATER SOLD BY THE COMPANY from all other Aperient Waters.

DEMAND THE 
DIAMOND MARK.

And insist upon receiving the HUNGARIAN APERIENT WATER of the APOLLINARIS COMPANY, LIMITED, London.

THE VALUE OF NUTRITION IN DISEASE.

All physicians who have ever used Murdock's Liquid Food and Suppositories recognize their value over all other foods, in breaking up disease and building up the patients after disease, preventing a relapse, **as the same results are obtained as in surgery.** Its value in surgical cases we illustrate by the records of the different cities and of Murdock's Free Surgical Hospital for Women, which is the largest in the United States. It contains 114 beds, every bed free, including operation, the operations ranging from 1000 to 1200 yearly, representing 90 of the worst classes known in surgery. Among these cases we have had **Cancer of uterus** (*Kolpo-hysterectomy*), 13; **Salpingitis** (*Tait's operation*), 31; **Fibroid of uterus** (*abdominal hysterectomy*), 19; **Ventral operation, hernia,** (*abdominal section*), 12; **Cancer of bowel** (*incision*), 2; **Parovarian cyst, 6; Papillomatous cyst** (*extirpation*), 4; **Tubercular peritonitis** (*incision*), 1, **Ovarian cystoma 27; Nymphomania** (*Battey*), 1; **Exploratory abdominal incisions, 12; Fibroid with abdominal abscess** (*Hegar*), 2; **Hysterorraphy, 2; Dermoid cyst, 3; Cirrhotic ovaries,** (*Battey*), 4; **Fibroid uterus** (*Hegar*), 6; **Hystero-epilepsy** (*Battey*), 1; **Haemato-Salpinx** (*Tait*), 5; **Rupture of intestine into vagina, 1; Dislocated kidney, 2; Fibroid tumor abdominal wall, 1; Resection of intestine** (*Senn*), 1; **Ruptured perineum, 294.** Patients are in the Hospital 8 days before and 26 days after operation, on an average.

In Boston, last year, 42 deaths were from Cancer in the Breast. In Murdock's Hospital, 35 such cases were operated on without a death, the patients remaining in the Hospital, on an average, 18 days.

Mortality in Boston,	25.60	per 1000.
" of Women in Boston,	29,00	" "
" in **Murdock's Free Surgical Hospital,**	**5.00**	" "
" New York,	26.32	" "
" Philadelphia,	20.00	" "
" Chicago,	20 90	" "
" St. Louis,	20.49	" "

showing our mortality is only one-sixth as great as of those in health. As good results were obtained in our General Hospital, which we kept open 27 months, **thus showing the value of nutrition as found in Murdock's Liquid Food, and so recognized by the British and American Medical Associations,** before which essays were read and discussed, and it is the only Raw food preparation on which essays were ever read.

Physicians are invited to visit our Hospitals and Works, also to send in patients and to be present at the operations. For any physician who has not used our Liquid Food (and Suppositories for adults and infants), we will deliver free samples to any express company in Boston.

When babies do not thrive, never change their food, but add five or more drops at each feeding of Murdock's Liquid Food, and their lost or needed vitality will be restored in less than thirty days. It is invaluable when weaning babies or when teething. If mothers will take one teaspoonful to a tablespoonful before each meal and on retiring, they will receive as much benefit as the baby.

Murdock Liquid Food Co., Boston.

CELERINA

NERVE TONIC, STIMULANT AND ANTISPASMODIC.

FORMULA.—Every Fluid Drachm represents FIVE grains EACH—Celery, Coca, Kola, Viburnum and Aromatics.

INDICATIONS.—Loss of Nerve-Power (so usual with Lawyers, Preachers, Writers and Business Men), Impotency, Spermatorrhea, Nervous Headache, Neuralgia, Paralysis, Hysteria, Opium Habit, Inebriety, Dyspepsia, and ALL LANGUID conditions of the System.

Indispensable to restore a patient after alcoholic excess.

DOSE.—One or two Teaspoonfuls three or more times a day, as directed by the Physician.

LIQUID IRON-RIO

Palatable and easily assimilated. Does not produce Nausea, nor irritate the Stomach. Does not Cause Headache, nor Constipate. Does not Stain the Teeth. It is so Acceptable to the Stomach that its Use is Admissible when all other forms of Iron would be rejected. Being so Readily Assimilable, it only requires a small Dose.

Each Fluid Drachm contains ONE GRAIN of Iron in a Pleasant and Digestible Form.

DOSE.—One or more Teaspoonfuls as indicated, during or after meals.

S. H. KENNEDY'S

CONCENTRATED EXTRACT OF

PINUS CANADENSIS

DARK. A NON-ALCOHOLIC LIQUID. WHITE.

A MOST VALUABLE NON-IRRITATING MUCOUS ASTRINGENT.

INDICATIONS.—Albuminuria, Diarrhea, Dysentery, Night-Sweats, Hemorrhages, Profuse Expectoration, Catarrh, Sore Throat, Leucorrhea, and other Vaginal Diseases, Piles, Sores, Ulcers, Burns, Scalds, Gonorrhea, Gleet, Etc.

When Used as an Injection, to Avoid Staining of Linen, the WHITE Pinus should be used.

RECOMMENDED BY PROMINENT EUROPEAN AND AMERICAN PHYSICIANS.

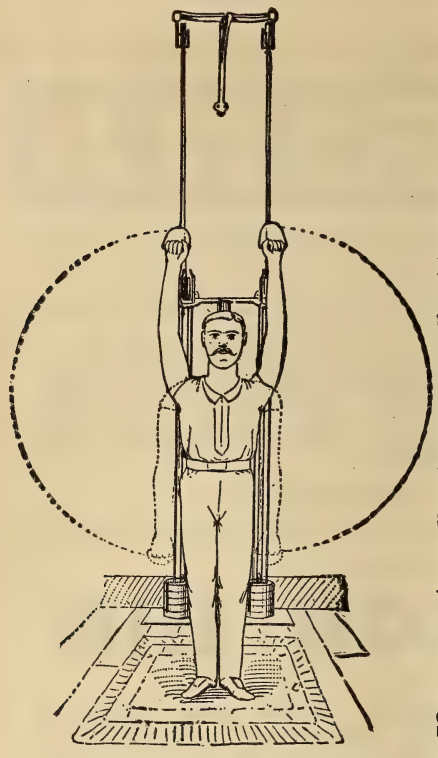
LONDON. PARIS. CALCUTTA. MONTREAL.



THE Medical Profession are cordially invited to visit our GYMNASIUM SHOW-ROOM containing over FIVE THOUSAND DOLLARS worth of apparatus for the advancement of physical culture.

Our O. K. Machine No. 2

Price, $10. Sent by Express to any part of the United States or Canada. No charge for casing.

Is endorsed by all Physicians who have seen it. It will develop any and every muscle of the body.

ADAPTED TO OLD AND YOUNG, MALE AND FEMALE.

We will mail our Manual of Physical Culture, together with complete catalogue, free, on application.

SPECIAL DISCOUNT TO THE PROFESSION.

A. J. REACH & CO.
1022 Market Street,
PHILADELPHIA.

SPORTING AND ATHLETIC GOODS OF EVERY DESCRIPTION.

No Chemicals.

W. BAKER & CO.'S Breakfast Cocoa

Is Absolutely Pure, and it is Soluble.

To increase the solubility of the powdered cocoa, various expedients are employed, most of them being based upon the action of some alkali, potash, soda or even ammonia. Cocoa which has been prepared by one of these chemical processes, can usually be recognized at once by the distinct alkaline reaction of the infusion in water.

W. Baker & Co.'s Breakfast Cocoa is manufactured from the first stage to the last by perfect mechanical processes, **no chemical being used in its preparation.** By one of the most ingenious of these mechanical processes the greatest degree of fineness is secured without the sacrifice of the attractive and beautiful red color which is characteristic of an absolutely pure and natural cocoa.

BOUDAULT'S PEPSINE

The only Pepsine used in the Hospitals of Paris for the last Thirty Years.

Unlike the various substitutes which, in most cases, are but unscientific or incompatible compounds, forced upon the Medical Profession as aids to digestion by extensive advertising, but which, when submitted to the proper tests, are found to be useless as digestive agents, Pepsine is constantly gaining in the esteem of the careful practitioner.

Since the introduction of Pepsine by Boudault and Corvisart in 1854, the original BOUDAULT'S PEPSINE HAS BEEN AT ALL TIMES CONSIDERED THE BEST, as is attested by the awards it has received at the Expositions of 1867, 1868, 187 1873, in 1876 at the Centennial Exposition of Philadelphia, and in 1878 at the Paris Exposition.

The most reliable tests, carefully applied, will satisfy everyone that BOUDAULT'S PEPSINE HAS A MUCH HIGHER DIGESTIVE POWER than the best Pepsines now before the Profession, and is therefore especially worthy of their attention.

BOUDAULT'S PEPSINE is prepared in the form of Pepsine Acid and Pepsine Neutral. It is sold in bottles of one ounce, with a measure containing exactly five grains; also in bottles of four, eight, and sixteen ounces for dispensing.

BOUDAULT'S WINE OF PEPSINE

FORMULA OF DR. CORVISART.

The taste of Pepsine being perfectly disguised in this Wine, it may be recommended to persons who have difficulty in taking Pepsine in the form of Powder. This Wine is tested so that a tablespoonful of it is equal in digestive power to ten grains of Boudault's Pepsine in powder. Sold only in bottles of eight ounces.

TANRET'S PELLETIERINE

For the Treatment of Tape-Worm (Tænia Solium).

This New Tænifuge, the Active Alkaloid of Pomegranate Bark, has of late come into extensive use in France for the treatment of Tape-Worm (Tænia Solium). The results of numerous experiments with it at the Marine Hospitals of Toulon, St. Mandrier, etc., and in the Hospitals of Paris, St. Antoine, La Charité, Necker Beaujon, etc., have all been most satisfactory. Doctor Dujardin Beaumetz, Member of the Academy of Medicine, and Professor Laboulbene, in their report to the Society of Therapeutics, have given it their unqualified approval, after the most searching experiments. This preparation is pleasant to administer, and, if certain preliminaries are observed, success will be insured.

Sold only in bottles containing one dose.

DUCRO'S ALIMENTARY ELIXIR

A Combination uniting the properties of Alcoholic Stimulants and Raw Meat.

This preparation, which has been used with great success in the hospitals of Paris since 1868, is adapted to the treatment o all diseases requiring administration, in a small volume, of a tonic able to stimulate and support the vital forces, as *Pulmonar Phthisis, Depression and Nervous Debility, Adynamia, Malarious Cachexia, etc.*

Prepared by EMILE DURIEZ & CO., Successors to DUCRO & CIE, Paris.

KIRKWOOD'S INHALER

This is the only complete, reliable, and effective inhaler in use, arranged for the direct application of Muriate of Ammonia and other remedial agents in the state of vapor to the diseased parts of the air-passages in the treatment of catarrh and diseases of the throat and lungs. No heat or warm liquids required in its use.

It is entirely different from the various frail, cheap instruments that have been introduced.

KIRKWOOD'S INHALER is accompanied by testimonials of the highest professional character, together with carefully prepared formulas for use.

RETAIL PRICE, COMPLETE, $2.50.

☞ A liberal discount allowed to the trade and profession. For descriptive pamphlet or other information address

H. MARION SIMS, M.D., Professor of Gynæcology; Gynæcologist to St. Elizabeth Hospital and New York Infant Asylum.

WILLIAM F. FLUHRER, M.D., Professor of Genito-Urinary Surgery; Surgeon to Bellevue and St. Sinai Hospitals.

THE NEW YORK POLYCLINIC is a School of Clinical Medicine and Surgery for *Practitioners only*. No didactic lectures are given. The classes are limited. The demonstrations are made at the Polyclinic School and Hospital, and in the various Hospitals in New York City with which the Faculty are connected.

Session of 1889-'90 opens Monday, September 16th, 1889. Physicians matriculating for the Winter Session will be admitted to the Clinics from July 1st to September 14th, without additional charge. For further information and for catalogue, address

JOHN A. WYETH, M.D.,
Secretary of the Faculty,
Or WILLIS O. DAVIS, Clerk,
214, 216 & 218 East 34th Street, New York City.

UNIVERSITY OF MARYLAND
SCHOOL OF MEDICINE.

Eighty-third Annual Announcement, 1889-90. The next regular session will begin October 1st, 1889. A full course of didactic lectures, with ample clinical and dissecting-room facilities.

FACULTY:

GEORGE W. MILTENBERGER, M.D.,
Professor of Obstetrics.
CHRISTOPHER JOHNSON, M.D.,
Emeritus Professor of Surgery.
SAMUEL C. CHEW, M.D.,
Professor of Principles and Practice of Medicine and Hygiene.
FRANK DONALDSON, M.D.,
Emeritus Clinical Professor of Diseases of the Throat and Chest.
WILLIAM T. HOWARD, M.D.,
Professor of Diseases of Women and Children and Clinical Medicine.
JULIAN J. CHISOLM, M.D.,
Professor of Eye and Ear Diseases.
FRANCIS T. MILES M.D.,
Professor of Physiology and Clinical Professor of Diseases of Nervous System.

L. McLANE TIFFANY, M.D.,
Professor of Surgery.
J. EDWIN MICHAEL, M.D.,
Professor of Anatomy and Clinical Surgery.
I. EDMONSON ATKINSON, M.D.,
Professor of Materia Medica and Therapeutics, Clinical Medicine and Dermatology.
R. DORSEY COALE, PH.D.,
Professor of Chemistry and Toxicology.
JOHN NOLAND MACKENZIE, M.D.,
Clinical Professor of Diseases of the Throat and Nose.
HERBERT HARLAN, M.D.,
Demonstrator of Anatomy.

For catalogue and further information, address: **Dr. J. EDWIN MICHAEL, Dean, 937 Madison Avenue.**

DENTAL DEPARTMENT.

Eighth Annual Announcement. Next regular session begins October 1st, 1889. New and excellent Infirmary and Laboratory, with abundance of clinical material.

FACULTY:

FRED. J. S. GORGAS, M.D., D.D.S.,
Professor of Principles of Dental Science, Dental Surgery, and Dental Mechanism.
JAMES H. HARRIS, M.D., D.D.S.,
Professor of Operative and Clinical Dentistry.
I. EDMONSON ATKINSON, M.D.,
Professor of Materia Medica and Therapeutics.
FRANCIS T. MILES, M.D.,
Professor of Physiology.
L. McLANE TIFFANY, M.D.,
Clinical Professor of Oral Surgery.

J. EDWIN MICHAEL, M.D.,
Professor of Anatomy.
R. DORSEY COALE, PH.D.,
Professor of Chemistry.
JOHN C. UHLER, M.D., D.D.S.,
Demonstrator of Mechanical Dentistry.
CHAS. L. STEEL, M.D., D.D.S.,
Demonstrator of Operative Dentistry.
HERBERT HARLAN, M.D.,
Demonstrator of Anatomy.
AND EIGHT ASSISTANT DEMONSTRATORS.

For catalogue and other information, apply to **Dr. F. J. S. GORGAS, Dean, 845 Eutaw Street, Baltimore.**

Medico-Chirurgical College of Philadelphia.

JAS. E. GARRETSON, A.M., M.D., Professor of Oral and Clinical Surgery.

WM. H. PANCOAST, A.M., M.D., Professor of General, Descriptive, and Surgical Anatomy and Clinical Surgery.

GEO. E. STUBBS, A.M., M.D., Professor of Clinical Surgery.

WM. F. WAUGH, A.M., M.D., Professor of Principles and Practice of Medicine and of Clinical Medicine.

ABRAHAM S. GERHARD, A.M., M.D., Professor of Forensic and Clinical Medicine.

WM. S. STEWART, A.M., M.D., Professor of Obstetrics and Clinical Gynecology.

H. EARNEST GOODMAN, M.D., Professor of Principles and Practice of Surgery and Clinical Surgery.

P. D. KEYSER, A.M., M.D., Dean, Professor of Ophthalmology.

SAMUEL B. HOWELL, A.M., M.D., Professor of Chemistry.

JOHN V. SHOEMAKER, A.M., M.D., Professor of Materia Medica, Pharmacology, Therapeutics and Clinical Medicine.

E. E. MONTGOMERY, B.S., M.D., Professor of Gynecology.

JAS. M. ANDERS, Ph.D., M.D., Professor of Hygiene and Clinical Diseases of Children; Associate Professor of Physiology

JOHN V. SHOEMAKER, A.M., M.D., Clinical Professor Skin Diseases.

FRANK WOODBURY, A.M., M.D., Honorary Professor of Clinical Medicine.

WM. B. ATKINSON, A.M., M.D. Honorary Professor of Sanitary Science and Paediatrics.

The Regular Session begins September 30th, 1889, and continues until the middle of April. It is preceded by a Preliminary Session of three weeks, and followed by a Spring Session lasting until the middle of June.

Seats are issued in the order of matriculation, and are forfeitable if fees are not paid before November 1st.

Preliminary examination or equivalent degree, and a three years' graded course obligatory. A fourth year voluntary.

Instruction is given by lectures, clinical teaching and practical demonstrations. In the subjects of Anatomy, Pharmacy, Chemistry, Histology and Pathology the usual methods of instruction are largely supplemented by laboratory work.

Examinations are held at the close of each Regular Session upon the studies of the term. Although the degree of Doctor of Medicine is conferred at the end of the third year, a fourth year is earnestly recommended, at the end of which the degree of Doctor of Medicine *cum laude* is given.

FEES.

Matriculation, $5: first and second years. each, $100; third year (no graduation fee), $100; fourth year, free to those who have attended three sessions in this school, to all others, $100.

Extra charges only for material used in the laboratories and dissecting-room.

For further information or announcement, address,

E. E. MONTGOMERY, M.D., Secretary,
Medico-Chirurgical College,
Cherry, below 18th Street, Philadelphia, Penna.

Medical College of Ohio.

Medical Department of the University of Cincinnati.

The Seventy-first Annual Session will begin September 4, 1889, and continue until March 1, 1890.

FEES.—Matriculation Ticket, $5.00; General Lecture Ticket $75.00; Hospital Ticket, $5.00; Graduation Fee, $25.00.

For circulars, and further information, address
JAMES G. HYNDMAN, M.D., Secretary,
22 West Ninth Street, Cincinnati, Ohio

WESTERN PENNSYLVANIA MEDICAL COLLEGE

CITY OF PITTSBURGH.

SESSIONS OF 1889—90.

The REGULAR SESSION begins on the last Tuesday of September, and continues six months. During this session, in addition to four Didactic Lectures, two or three hours are daily allotted to Clinical Instruction. Attendance upon two regular courses of lectures is requisite for graduation. A three years' graded course is also provided. The SPRING SESSION embraces recitations, clinical lectures and exercises, and didactic lectures on special subjects; this session begins the second Tuesday in April, and continues ten weeks.

The laboratories are open during the collegiate year for instruction in chemistry, microscopy, practical demonstrations in medical and surgical pathology, and lessons in normal histology. Special importance attaches to "the superior clinical advantages possessed by this College." For particulars, see annual announcement and catalogue, for which, address the Secretary of Faculty, Prof. J. W. J. McKENNAN.

Business correspondence should be addressed to
PROF. W. J. ASDALE, 2107 Penn Avenue, Pittsburgh.

Woman's Medical College
OF BALTIMORE.

S. E. Cor. Druid Hill Ave. and Hoffman St., Baltimore, Md.

THE EIGHTH ANNUAL SESSION WILL BEGIN ON WEDNESDAY, OCTOBER 2d, 1889.

For further information or catalogue, address
RANDOLPH WINSLOW, M.D., Acting Dean,
No. 1, Mount Royal Terrace, Baltimore, Md.

Medical Department, State University of Iowa, at Iowa City, Iowa.

The next Session will begin on September 11, 1889, and continue until March 12, 1890. Attendance upon three courses of lectures, of six months each, is requisite to graduation. The facilities for dissection and clinical study are unsurpassed.

TERM EXPENSES—Lecture Ticket, $20.00; Demonstrator's Ticket, $10.00; Matriculation Ticket, $5.00 (paid but once); Hospital Ticket, $1.00; Examination Fee (for final examination) $25.00. No charge for dissecting material. For further information, address DR. A. C. PETERS, Ast. Sec'y, Iowa City, Iowa.

THE
College of Physicians and Surgeons
OF CHICAGO.

Regular Session opens Sept. 23, 1889.

GRADED COURSE OF INSTRUCTION.

Excellent Clinical Advantages.

The College Building (directly opposite Cook County Hospital) is one of the most complete and elaborate edifices devoted to medical teaching in this country.

FEES.—WINTER SESSION.—Matriculation (paid annually), $5 00. General Ticket, admitting to all the lectures and including all practical work in the chemical and physiological laboratories, $60.00. For further information or announcements, address

PROF. W. E. QUINE, Secretary,
Or 3160 Indiana Avenue.
PROF. A. REEVES JACKSON, President,
271 Michigan Avenue, Chicago, Illinois.

DETROIT COLLEGE OF MEDICINE.

SESSION 1889-90.

Clinical and Practical teaching are made an important feature of this College. Clinical instruction is given daily at HARPER, ST. MARY'S and ST. LUKE'S HOSPITAL, at the COLLEGE, at COLLEGE EYE and EAR INFIRMARY, ST. MARY'S FREE EYE and EAR INFIRMARY, and at the three FREE DISPENSARIES. The facilities offered by this college are unsurpassed for the practical study of MEDICINE, SURGERY, OBSTETRICS, GYNÆCOLOGY, DISEASES OF CHILDREN, GENITO-URINARY, and ORTHOPÆDIC SURGERY, OPHTHALMOLOGY and OTOLOGY, DERMATOLOGY and LARYNGOLOGY.

REGULAR SESSION opens on Wednesday, Sept. 25, and continues six months. During the session, the Professors will take special pains to examine the Students upon the subjects of the previous lectures.

SPRING SESSION begins April 2d, 1890; and closes June 11th.

FEES.—Matriculation fee, $5; Fees for Regular Session, $50; Spring Session, $10, to those who attend the regular term—to all others, $25; Hospital Fee, $10; Graduation Fee, $30; Perpetual Ticket, $100.

For further particulars, and for College Circular, apply to

H. O. WALKER, M.D., Secretary,
33 Lafayette Ave., Detroit, Mich.

UNIVERSITY OF PENNSYLVANIA.—Medical Department.

The 124TH ANNUAL WINTER SESSION will begin Tuesday, October 1st, 1889, at 12 M., and continue until May 1st, 1890.

The PRELIMINARY SESSION begins September 18th, 1889.

The curriculum is graded and three annual winter sessions are required. Practical instruction, including laboratory work in Chemistry, Histology, Osteology and Pathology, with Bedside Instruction in Medicine, Surgery and Gynecology are a part of the regular course and without additional expense.

FACULTY.

JOSEPH LEIDY, M.D., LL.D., Professor of Anatomy.
D. HAYES AGNEW, M.D., LL.D., Honorary Professor of Clinical Surgery.
WILLIAM PEPPER, M.D., LL.D., Professor of Theory and Practice of Medicine, and of Clinical Medicine.
WILLIAM GOODELL, M.D., Professor of Gynecology.
JAMES TYSON, M.D., Professor of Clinical Medicine.

COLDEN'S LIQUID BEEF TONIC

AN INVALUABLE AID IN MEDICAL PRACTICE.

ORIGINAL | COLDEN'S LIEBIG'S LIQUID EXTRACT OF BEEF AND TONIC INVIGORATOR. | LABEL.

ESSENTIALLY DIFFERENT FROM ALL OTHER BEEF TONICS. UNIVERSALLY ENDORSED BY LEADING PHYSICIANS.

This preparation, consisting of the Extract of Beef (prepared by Baron Liebig's process), the best Brandy obtainable, soluble Citrate of Iron, Cinchona and Gentian is offered to the Medical Profession upon its own merits. It is of inestimable value in the treatment of **Debility, Convalescence from Severe Illness Anæmia, Malarial Fever, Chlorosis, Incipient Consumption, Nervous Weakness,** and maladies requiring a Tonic and Nutrient. It is quickly absorbed by the Stomach and upper portion of the Alimentary Canal, and therefore finds its way into the circulation quite rapidly.

COLDEN'S LIQUID BEEF TONIC appeals to the judgment of intelligent Physicians in the treatment of

ALL CASES OF GENERAL DEBILITY.

By the urgent request of several eminent members of the medical profession, I have added to each wineglassful of this preparation two grains of Soluble Citrate of Iron, and which is designated on the label, **"With Iron, No. 1;"** while the same preparation, **Without Iron,** is designated on the label as **"No. 2."**

In prescribing this preparation, physicians should be particular to mention *"COLDEN'S,"* viz., *"Ext. Carnis Fl. Comp. (Colden.)"* A Sample of **COLDEN'S BEEF TONIC** will be sent free on application, to any physician (enclosing business card) in the United States. ***Sold by druggists generally.***

FELLOWS'
HYPO-PHOS-PHITES

(SYR: HYPOPHOS: COMP: FELLOWS)

Contains **The essential elements** to the Animal Organization—Potash and Lime.

The **Oxydizing Agents**—Iron and Manganese;

The **Tonics**—Quinine and Strychnine,

And the **Vitalizing Constituent**—Phosphorus,

Combined in the form of a Syrup, with *slight alkaline reaction.*

It Differs in Effect from all others, being pleasant to taste, acceptable to the stomach, and harmless under prolonged use.

It has Sustained a High Reputation in America and England for efficiency in the treatment of Pulmonary Tuberculosis, Chronic Bronchitis, and other affections of the respiratory organs, and is employed also in various nervous and debilitating diseases with success.

Its Curative Properties are largely attributable to Stimulant, Tonic, and Nutritive qualities, whereby the various organic functions are recruited.

In Cases where innervating constitutional treatment is applied, and tonic treatment is desirable, this preparation will be found to act with safety and satisfaction.

Its Action is Prompt; stimulating the appetite and the digestion, it promotes assimilation, and enters directly into the circulation with the food products.

The Prescribed Dose produces a feeling of buoyancy, removing depression or melancholy, and hence is of great value in the treatment of MENTAL AND NERVOUS AFFECTIONS.

From its exerting a double tonic effect and influencing a healthy flow of the secretions, its use is indicated in a wide range of diseases.

Champagne ANALYZED

Of Interest to all Medical Practitioners.

WHAT IS SAID BY

THOMAS KING CHAMBERS, M.D., F.R.C.P.
R. OGDEN DOREMUS, M.D.
F. W. PAVY, M.D., F.R.S.

"Champagne, with a minimum of alcohol, is by far the wholesomest, and possesses remarkable exhilarating power."—THOMAS KING CHAMBERS, M.D., F.R.C.P.

"Having occasion to investigate the question of wholesome beverages, I have made a chemical analysis of the most prominent brands of Champagne. I find G. H. Mumm & Co.'s Extra Dry to contain, in a marked degree, less alcohol than the others. I therefore most cordially commend it not only for its purity but as the most wholesome of the Champagnes."—R. OGDEN DOREMUS, M.D., *Professor of Chemistry, Bellevue Hospital Medical College, New York.*

"Champagne, while only possessing the alcoholic strength of natural wines, is useful for exciting the flagging powers in case of exhaustion."—F. W. PAVY, M.D., F.R.S., *Lecturer on Physiology at Guy's Hospital, London.*

The remarkable vintage of 1884 of **C. H. MUMM & CO.'S EXTRA DRY CHAMPAGNE,** the finest for a number of years, is now imported into this market, and pronounced by connoisseurs unsurpassed for excellence and bouquet.

ACCIDENTS AND EMERGENCIES

By CHARLES W. DULLES, M.D.

"A work that ought to be in every home, and every home that has a copy kept where it can be consulted at short notice is likely to find it worth many times its small cost."—*Philadelphia Evening Telegraph*, May 5, 1888.

"The methods of treatment recommended are trustworthy and reliable. The manual is one of the best of this class of books and should be in the library of every householder, ready for reference at a moment's notice."—*Science*, May 18, 1888.

Sent on receipt of 75 Cents.

ADDRESS:

Publisher **Medical and Surgical Reporter,**

P.O. Box 843. PHILADELPHIA, PA.

The utility of artificial legs and arms with rubber feet and hands is evidenced by the operations of over nine thousand men, women, and children distributed throughout the entire civilized world. Strange as it may seem, this army mingles with the vast populace and their misfortunes are lost to sight. Men engaged in all manner of vocations, manual, arduous, menial, on the farm, at the forge, in the mines, at the desk. Women attend to their household duties, whether in the kitchen, laundry, drawing-room, or parlor. Children wearing one or a pair of artificial limbs are no longer objects of pity and dependence; they indulge with other children in all manner of sports, they skate, ride the bicycle, romp and tumble about just as healthy and merry children should do.

One little fellow from Connecticut writes: "I can climb trees, play base-ball, and other out-door games as well as other 14-year-old boys."

A large illustrated book, containing 400 pages and over 200 illustrations, will be sent free to those needing artificial legs and arms, or to physicians and others interested.

This book gives instructions how to order and be fitted while the subject remains at home.

A. A. MARKS, 701 Broadway, New York City.

ESTABLISHED OVER 36 YEARS.

McARTHUR'S SYRUP.

(SYR: HYPOPHOS: COMP: C. P. McARTHUR.)

Its use is indicated in Consumption and Tuberculosis, Diseases of the Chest, Chronic Cough, Throat Affections, General Debility, Brain Exhaustion, Impotence and Loss of Memory.

The point of primary importance in the use of the Hypophosphites is their *chemical* purity, but unfortunately they are too often adulterated.

So little seems to be generally known, even among the medical profession, with regard to the chemistry of the Hypophosphites, and the absolute necessity of CHEMICAL purity, that we call attention to this point.

One of the first effects produced by the use of our CHEMICALLY PURE Hypophosphites is a general increase of nervous energy, with a feeling of ease and comfort.

The second effect is an increase of appetite; digestion is improved, and the bowels become regular in their action, the quantity and color of the blood is increased, respiration is controlled, a better expansion of the chest is observed, cough improves, easy expectoration is produced, night perspiration diminishes, the face becomes fuller, the lips red, the nails and hair grow, and in children the teeth, showing the importance of the Hypophosphites on the organ of nutrition.

☞ Physicians when prescribing will please write thus:

℞ SYR: HYPOPHOS: COMP: McARTHUR. ONE BOTTLE.

As it is made *only for physicians* there are no printed wrappers or advertisements about the bottle.

Our pamphlet on the **CURABILITY AND TREATMENT OF CONSUMPTION,** sent free to physicians upon application.

We will send one bottle of McArthur's Syrup to any physician, without charge, who will pay the express charges on the same.

Mention this Journal. McARTHUR HYPOPHOSPHITE CO., BOSTON, Mass.

THE NEW HYPNOTIC
SULFONAL-BAYER.

SULFONAL was discovered by Prof. Eugen A. Baumann, of Freiburg University, and was first prepared by the Farbenfabriken vorm. Friedr. Bayer & Co., Elberfeld.

SULFONAL (Diæthylsulfondimethylmethan) is in the form of colorless prisms, odorless, and tasteless, melting at 125.5° C. (258° F.) and has the composition $(C\ H_3)_2{=}C{=}(C_2\ H_5\ SO_2)_2$. It is slightly soluble in cold water, but easily soluble in hot water or alcohol.

SULFONAL was first examined as to its physiological and pathological effects by Prof. A. Kast, of Freiburg University, and its hypnotic action was discovered and studied by him.

Since then SULFONAL has been the subject of numerous trials and experiments by many eminent and experienced physicians. Their testimony is unanimously favorable, and the conclusions reached by them are as follows:

SULFONAL is a prompt and reliable hypnotic, which in proper doses, produces quiet, natural sleep, lasting a number of hours.

SULFONAL has no unfavorable effects on the heart and the circulation, nor on the temperature, the pulse, or the respiration.

SULFONAL produces no disagreeable secondary symptoms; the patients with very few exceptions awake from their sleep feeling strong and greatly refreshed.

SULFONAL does not interfere with the process of digestion.

SULFONAL is a hypnotic, and not a narcotic; it acts by giving rest to the cells of the cerebral cortex, thereby causing sleep.

SULFONAL does not create an unconquerable desire for its repeated use; there is no danger of a SULFONAL-habit. Neither is it necessary to increase the dose after long-continued use.

SULFONAL is best administered at supper-time, dissolved in hot liquids, *e. g.*, a bowl of soup or broth, a cup of milk, tea, coffee, cocoa, etc.

These points will be found to be fully exhibited in the series of contributions contained in our pamphlet, which will be mailed on application.

SULFONAL-BAYER is supplied by us in half-ounce and one-ounce vials.

We prepare 5-grain and 15-grain Tablets of Sulfonal-Bayer. The tablet form is admirably adapted to the purpose of administering this drug, as when they are placed in the liquids, they disintegrate and are thus received into the system.

We also put up Sulfonal-Bayer in the form of our Soluble Pills, containing five grains each.

THE NEW ANTIPYRETIC
PHENACETINE-BAYER.

Phenacetine-Bayer (Para-Acetphenetidine) is a white, glossy, crystalline powder, perfectly tasteless, melting at 135° C.=307° F and has the composition $C_6\ H_4 < {}^{O.C_2H_5}_{NH(CO{-}CH_3)}$.

It is slightly soluble in water, a little more soluble in glycerine, but most freely in alcohol.

Phenacetine-Bayer was first prepared by the Farbenfabriken, formerly Friedr. Bayer & Co., Elberfeld, and is of absolute purity and uniform quality.

Summarizing the superiority of Phenacetine-Bayer over other antipyretics and antineuralgics, the following conclusions are formed:

1. ***Phenacetine-Bayer is an efficacious antipyretic.***
2. ***It does not develop any disagreeable or noxious after-effects.***
3. ***The dose required is half that of Antipyrine.***
4. ***It is perfectly tasteless.***
5. ***On account of its innocuousness and tastelessness, it is a valuable antipyretic both in adults and in children.***
6. ***Phenacetine-Bayer is an important antineuralgic; its effect is more energetic than that of Antipyrine and does not cause lassitude or any other disagreeble symptoms.***

Our pamphlet on Phenacetine-Bayer, containing the valuable testimony of eminent physicians will be mailed on application.

We offer Phenacetine-Bayer in one-ounce vials, or in the form of our Soluble Pills of the strength of two and four grains to each pill.

W. H. SCHIEFFELIN & CO.,

170 & 172 WILLIAMS STREET, NEW YORK,

SOLE LICENSEES AND SOLE AGENTS FOR THE UNITED STATES

SUCCUS ALTERANS

(McDADE.)

SUCCUS ALTERANS is a purely vegetable compound of the preserved juices of Stillingia Sylvatica Lappa Minor, Phytolacca Decandra, Smilax Sarsaparilla, and Xanthoxylum Carolinianum, as collected by Dr. Geo. W. McDade, exclusively for Eli Lilly & Co., and endorsed by Dr. J. Marion Sims.

SUCCUS ALTERANS continues to gain favor from its remarkable Alterative and Tonic properties, *eliminating specific poison from the blood* and *increasing the proportion of red corpuscles in anæmic patients* to a wonderful degree; is endorsed by the medical profession, and in use by many hospitals of note.

SUCCUS ALTERANS in venereal and cutaneous diseases is fast supplanting Mercury, the Iodides, and Arsenic; and is a certain remedy for Mercurialization, Iodism, and the dreadful effects often following the use of Arsenic in skin diseases.

SUCCUS ALTERANS is also strongly recommended for its Tonic and Alterative effects in myriad forms of scrofulous disease, and in all cases where anæmia is a factor. Such patients rapidly develop a good appetite, sleep soundly, and gain flesh rapidly. Many cases are on record where patients increased ten to twenty-five pounds in weight in a few weeks.

SUCCUS ALTERANS is giving satisfactory results in treatment of *Chronic Rheumatism*, and can be used with confidence.

SUCCUS ALTERANS may be given for any length of time, without injury to the patient.

SUCCUS ALTERANS is put up in pint round amber bottles, and *never in bulk.*

PHYSICIANS who have not received Dr. McDade's latest publication, the Monographia Syphilitica, should send their address, mentioning this journal, and we will mail a copy. It contains a paper, illustrated with colored plates, by Dr. D. H. Goodwillie, of New York, on the "Sequelæ of Syphilis," reports of cases in practice, and many other valuable papers.

ELIXIR PURGANS.

Elixir Purgans (Lilly) reliably stimulates the dormant liver without undue irritation, and has gentle yet positive effect upon the alimentary tract. In Habitual Constipation, so common in Women and Children, it will be found particularly useful. Its endorsement at Bellevue and many other prominent hospitals East and West, as well as its employment in general practice by the most eminent medical men, confirms the experience of years in its use.

Each Teaspoonful Represents	
Rhamnus Purshiana, -	10 grs.
Euonymus Atropur., - -	8 grs.
Cassia Acutifolia (Purif.)	10 grs.
Iris Versicolor, - - -	4 grs.
Hyoscyamus Niger, -	2 grs.
Aromatics, etc.	

IN PRESCRIBING, PLEASE BE CAREFUL TO WRITE

ELIXIR PURGANS (LILLY),

THAT OTHER PREPARATIONS MAY NOT BE SUBSTITUTED.

HIGHLY RECOMMENDED.

We take pleasure in endorsing the Elixir Purgans (Lilly) as prepared from the above formula for in it we find a near approach to positive *perfection* in the form of a *Liquid Cathartic*, and, from our experience with the preparation, can highly recommend it to the profession.

JAMES R. HEALY, M.D., *Sup't Infants' and Children's Hospital, Randall's Island, N. Y.*

GRAND NATIONAL PRIZE OF 16,600 FRANCS,

QUINA-LAROCHE

This meritorious **Elixir, QUINA-LAROCHE,** is prepared from the **three** Cinchonas; it is an agreeable and doubtless highly efficacious remedy.

—*The Lancet.*

VINOUS ELIXIR,

A STIMULATING RESTORATIVE

—AND—

ANTI-FEBRILE TONIC.

QUINA-LAROCHE under the form of a vinous **Elixir** contains the totality of the numerous principles of the **three** Cinchona barks. It is a preparation which renders great services to Therapeutics.—Extract of the *Gazette des Hôpitaux,* Paris.

FAR SUPERIOR TO ALL ORDINARY CINCHONA WINES.

LAROCHE'S QUINA, tried by the Academy of Medicine of Paris, is a specially prepared COMPOUND EXTRACT of Quinquina, a careful analysis, confirmed by experience, has shown that most of the wines and syrups hitherto used have not contained all the properties of this precious bark, of these some, although beneficial, are altogether lost, while many preparations contain but half the properties of the bark in varying proportions.

MR. LAROCHE, by his peculiar method, has succeeded in extracting all the active principles of the quinquina, combining these with *Catalan Wine* forming an Elixir free from the disagreeable bitterness of other similar preparations. Practitioners have found triple advantages in the use of this Elixir, it is a *strong tonic,* is easily administered, and perfectly harmless, being free from the unpleasant effects of Quinine.

THE FERRUGINOUS QUINA-LAROCHE is the invigorating tonic *par excellence,* having the advantage of being easily assimilated by the gastric juice; without, in any way, deranging the action of the digestive organs, proving itself to be a most efficacious remedy in cases of impoverishment of the blood, ANÆMIA, CHLOROSIS, INTESTINAL HÆMORRHAGE, CASTRALGIA, EXHAUSTION, ETC., ETC.

BROMIDIA

THE HYPNOTIC.

FORMULA.—

Every fluid drachm contains 15 grains EACH of Pure Chloral Hydrat. and purified Brom. Pot., and one-eighth grain EACH of gen. imp. ext. Cannabis Ind. and Hyoscyam.

DOSE.—

One-half to one fluid drachm in WATER or SYRUP every hour, until sleep is produced.

INDICATIONS.—

Sleeplessness, Nervousness, Neuralgia, Headache, Convulsions, Colic, Mania, Epilepsy, Irritability, etc. In the restlessness and delirium of fevers it is absolutely invaluable.

IT DOES NOT LOCK UP THE SECRETIONS.

PAPINE

THE ANODYNE.

Papine is the Anodyne or pain-relieving principle of Opium, the Narcotic and Convulsive Elements being eliminated. It has less tendency to cause Nausea, Vomiting, Constipation, Etc.

INDICATIONS.—

Same as Opium or Morphia.

DOSE.—

(ONE FLUID DRACHM)—represents the Anodyne principle of one-eighth grain of Morphia.

IODIA

The Alterative and Uterine Tonic.

FORMULA.—

Iodia is a combination of active principles obtained from the Green Roots of Stillingia, Helonias, Saxifraga, Menispermum, and Aromatics. Each fluid drachm also contains five grains Iod. Potas., and three grains Phos. Iron.

DOSE.—

One or two fluid drachms (more or less as indicated) three times a day before meals.

INDICATIONS.—

Syphilitic, Scrofulous and Cutaneous Diseases, Dysmenorrhea, Menorrhagia, Leucorrhea, Amenorrhea, Impaired Vitality, Habitual Abortions, and General Uterine Debility.

THE SUSTAINED SUPREMACY

OF

Fairchild's Pepsin,

In ACTIVITY, PERMANENCE and GENERAL EXCELLENCE

Has won for this product a wide use and recognition in all the principal markets of the world.

We guarantee it to be unchangeable, to maintain its activity and quality under all ordinary commercial conditions; it is therefore, by far the most available for the dispensing counter, as well as in the manufacture of every form of pepsin preparation.

Under exactly parallel conditions, with any proper percentage of acidity and with any proportion of such acidulated water to the albumen, Fairchild's pepsin is positively superior to any pepsin known.

It will, under absolutely comparative conditions, grain for grain, digest more albumen than any other pepsin made.

We will be pleased to send samples to any physician who may wish to ascertain for himself the relative activity of Fairchild's pepsin, or to submit it to any practical trial.

Prices and complete information upon application.

FAIRCHILD BROS. & FOSTER,

SVAPNIA

OR

PURIFIED OPIUM

FOR PHYSICIANS USE ONLY.

Contains the Anodyne and Soporific Alkaloids, Codeia, Narceia and Morphia.

Excludes the Poisonous and Convulsive Alkaloids, Thebaine, Narcotine and Papaverine.

SVAPNIA has been in steadily increasing use for over twenty years, and whenever used has given great satisfaction.

To PHYSICIANS OF REPUTE, not already acquainted with its merits, samples will be mailed on application.

SVAPNIA is made to conform to a uniform standard of Opium of Ten per cent. Morphia strength.

JOHN FARR, Manufacturing Chemist, New York.

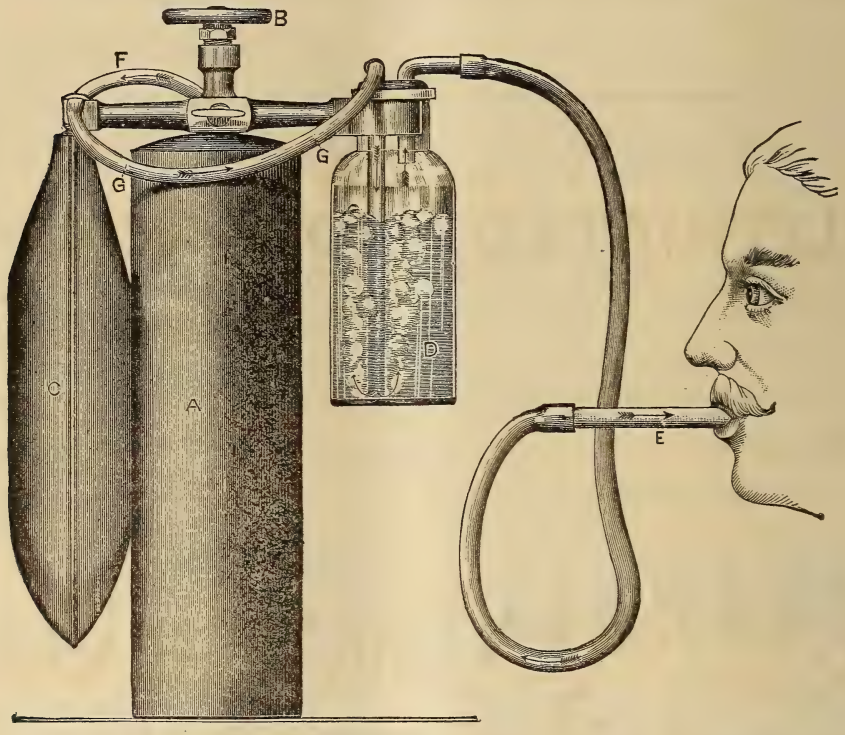
INHALATION APPARATUS

FOR

THE THERAPEUTIC ADMINISTRATION OF OXYGEN.



In the treatment of lung troubles by Oxygen its exhibition by inhalation is preferred. The apparatus herewith shown is a modification of the Nitrous Oxide apparatus which we have supplied for many years. It is made in the best manner throughout, and is the outcome of years of experience in the manufacture of gas apparatus. It will be found to meet all the requirements.

We supply the gas in two sizes of cylinders, containing respectively forty and one hundred gallons, either pure Oxygen, or a mixture of Oxygen and Nitrous Oxide in definite proportions of 20 per cent., and forty per cent. of Nitrous Oxide.

Whether pure or mixed the gas is sold at the uniform price of 5 cents a gallon. The cost of the cylinders will be refunded on their return empty with the valves in good condition. Full description of Inhalation and Enema apparatuses with directions for use accompany each apparatus, or will be supplied on application.

PRICES.

Inhalation Apparatus	$5.00
Cylinder, 40 gallons' capacity	6.00
40 gallons Gas, either pure Oxygen or mixed Oxygen and Nitrous Oxide	2.00
Complete Apparatus, Cylinder, and 40 gallons Gas	$13.00
Inhalation Apparatus	$5.00
Cylinder, 100 gallons' capacity	15.00
100 gallons Gas, either pure or mixed	5.00
Complete Apparatus, Cylinder, and 100 gallons Gas	$25.00

THE BEST ANTISEPTIC
FOR BOTH INTERNAL AND EXTERNAL USE.

ANTISEPTIC, PROPHYLACTIC, DEODORANT.

LISTERINE

NON-TOXIC, NON-IRRITANT, NON-ESCHAROTIC.

FORMULA—Listerine is the essential antiseptic constituent of Thyme, Eucalyptus, Baptisia, Gaultheria and Mentha Arvensis, in combination. Each fluid drachm also contains two grains of refined and purified Benzo-boracic Acid.

DOSE—Internally: One teaspoonful three or more times a day (as indicated) either full strength, or diluted, as necessary for varied conditions.

LISTERINE is a well-proven antiseptic agent—an antizymotic—especially adapted to internal use, and to make and maintain surgical cleanliness—asepsis—in the treatment of all parts of the human body, whether by spray, irrigation, atomization, or simple local application, and therefore characterized by its particular adaptability to the field of

PREVENTIVE MEDICINE—INDIVIDUAL PROPHYLAXIS.

Diseases of the Uric Acid Diathesis.

LAMBERT'S

LITHIATED HYDRANGEA

KIDNEY ALTERATIVE—ANTI-LITHIC.

FORMULA—Each fluid drachm of "Lithiated Hydrangea" represents thirty grains of FRESH HYDRANGEA and three grains of CHEMICALLY PURE Benzo-Salicylate of Lithia. Prepared by our improved process of osmosis, it is INVARIABLY of DEFINITE and UNIFORM therapeutic strength, and hence can be depended upon in clinical practice.

DOSE—One or two teaspoonfuls four times a day (preferably between meals).

Urinary Calculus, Gout, Rheumatism, Bright's Disease, Diabetes, Cystitis, Hæmaturia Albuminuria, and Vesical irritations generally.

We have much valuable literature upon { GENERAL ANTISEPTIC TREATMENT, LITHEMIA, DIABETES, CYSTITIS, ETC. } To forward to Physicians upon request:

LAMBERT PHARMACAL CO., ST. LOUIS, MO.

CALIFORNIA VINTAGE CO.

21 PARK PLACE N.Y.

Geo Hamlin Prest. Chas Roome Parmele Treas.

GENTLEMEN:

The Case of your wines sent me for analysis by Dr. A. L. Hummel, of the "Annals of Hygiene," containing specimens of your La Rosa Zinfandel, Mataro, Riesling, Royal Tokay, and Royal Grape Brandy, has been duly received.

I have examined them for the common contaminants of wine; to wit: Sulphurous acid and sulphites, salicylic acid, fuchsin, lead salts, etc., none of which I found present therein.

I have also determined their alcoholic strength, extractives, and ashes, and found them to correspond strictly in this respect with the standard of pure and natural wines, which cannot be said of many of the imported wines.

As a native of a wine-producing country, I consider myself somewhat of a judge of wines, and regard your products as comparing more than favorably with most of the wines from abroad which are sold at higher prices, so much so that I enclose within my order for fifty bottles of La Rosa Zinfandel, which I expect to use hereafter exclusively at my table.

Very Respectfully,

L. WOLFF, M.D.,
Demonstrator of Chemistry, Jefferson Medical College.

NON-ALCOHOLIC. NON-RESINOUS.

BLAND AND NON-IRRITATING.

Fluid Hydrastis.

A solution of definite strength and reliability, representing all the valuable constituents of the drug—the offensive and irritating resins being rejected. The only perfect representative of the drug in the fluid form within reach of the medical profession. Though often attempted, it has never been successfully imitated.

Send for our pamphlet on "Hydrastis and its Preparations."

☞ *Physicians who have been disappointed in the use of favorite Prescriptions have the remedy in their own hands.*

Prescriptions and orders should read "Wm. S. M. Chem. Co."

GREEN DRUG
FLUID EXTRACTS.

——CHARACTERISTICS.——

Uniform Strength, Convenience of administration,
Non-liability to deterioration by age,
Positive therapeutic efficacy.

The WM. S. MERRELL CHEMICAL CO. will not hold themselves responsible for the identity of Fluid Extracts, filled out by druggists from bulk stock, even though the written label may read *"Merrell's."*

CAUTION—accept original packages only.

☞ *Read our Monograph—Green Drug Fluid Extracts—Their origin, history, and rationale.*

Sent free to any address.

PRICE REDUCED.

True Salicylic Acid.

CRYSTALLIZED FROM

WINTERGREEN OIL.—ITS NATURAL SOURCE.

DR. P. W. LATHAM, Downing Professor of Medicine at Cambridge (England), lecturing on the treatment of gout and rheumatism at the Royal College of Physicians, says:

"The true Salicylic Acid obtained from the vegetable kingdom must alone be employed. If you have to give large doses, avoid giving the artificial product obtained from carbolic acid, however much it may have been dialyzed and purified. Give the acid without any alkali or base," etc.

A reprint of this exceedingly valuable paper will be sent on application.

A DESIDERATUM—not always appreciated.

The quality of medicines used in the prescription is as important a factor in the cure of disease as a correct diagnosis; and a physician violates no code, either of ethics or morals, in demanding of his druggist that which he knows to be reliable, instead of leaving to the latter to decide whose preparations he shall or shall not use.

THE VALUE OF NUTRITION IN DISEASE.

All physicians who have ever used Murdock's Liquid Food and Suppositories recognize their value over all other foods, in breaking up disease and building up the patients after disease, preventing a relapse, **as the same results are obtained as in surgery.** Its value in surgical cases we illustrate by the records of the different cities and of Murdock's Free Surgical Hospital for Women, which is the largest in the United States. It contains 114 beds, every bed free, including operation, the operations ranging from 1000 to 1200 yearly, representing 90 of the worst classes known in surgery. Among these cases we have had **Cancer of uterus** (*Kolpo-hysterectomy*), 13; **Salpingitis** (*Tait's operation*), 31; **Fibroid of uterus** (*abdominal hysterectomy*), 19; **Ventral operation, hernia,** (*abdominal section*), 12; **Cancer of bowel** (*incision*), 2; **Parovarian cyst, 6; Papillomatous cyst** (*extirpation*), 4; **Tubercular peritonitis** (*incision*), 1, **Ovarian cystoma 27; Nymphomania** (*Battey*), 1; **Exploratory abdominal incisions, 12; Fibroid with abdominal abscess** (*Hegar*), 2; **Hysterorraphy, 2; Dermoid cyst, 3; Cirrhotic ovaries,** (*Battey*), 4; **Fibroid uterus** (*Hegar*), 6; **Hystero-epilepsy** (*Battey*), 1; **Haemato-Salpinx** (*Tait*), 5; **Rupture of intestine into vagina, 1; Dislocated kidney, 2; Fibroid tumor abdominal wall, 1; Resection of intestine** (*Senn*), 1; **Ruptured perineum, 294.** Patients are in the Hospital 8 days before and 26 days after operation, on an average.

In Boston, last year, 42 deaths were from Cancer in the Breast. In Murdock's Hospital, 35 such cases were operated on without a death, the patients remaining in the Hospital, on an average, 18 days.

Mortality in Boston,	25.60	per	1000.
" of Women in Boston,	29,00	"	"
" in **Murdock's Free Surgical Hospital,**	**5.00**	"	"
" New York,	26.32	"	"
" Philadelphia,	20.00	"	"
" Chicago,	20.90	"	"
" St. Louis,	20.49	"	"

showing our mortality is only one-sixth as great as of those in health. As good results were obtained in our General Hospital, which we kept open 27 months, **thus showing the value of nutrition as found in Murdock's Liquid Food, and so recognized by the British and American Medical Associations,** before which essays were read and discussed, and it is the only Raw food preparation on which essays were ever read.

Physicians are invited to visit our Hospitals and Works, also to send in patients and to be present at the operations. For any physician who has not used our Liquid Food (and Suppositories for adults and infants), we will deliver free samples to any express company in Boston.

When babies do not thrive, never change their food, but add five or more drops at each feeding of Murdock's Liquid Food, and their lost or needed vitality will be restored in less than thirty days. It is invaluable when weaning babies or when teething. If mothers will take one teaspoonful to a tablespoonful before each meal and on retiring, they will receive as much benefit as the baby.

Murdock Liquid Food Co., Boston.

ALETRIS CORDIAL

UTERINE TONIC AND RESTORATIVE.

Prepared from the Aletris Farinosa or True Unicorn and Aromatics.

INDICATIONS.

Amenorrhea, Dysmenorrhea, Leucorrhea, Prolapsus Uteri, Sterility, to Prevent Miscarriage, Etc.

DOSE:—ONE TEASPOONFUL THREE OR FOUR TIMES A DAY.

UNRIVALED AS A UTERINE TONIC IN IRREGULAR, PAINFUL, SUPPRESSED AND EXCESSIVE MENSTRUATION.

It Restores Normal Action to the Uterus, and Imparts Vigor to the Entire Uterine System.

☞Where women have miscarried during previous pregnancies, or in any case where miscarriage is feared, the ALETRIS CORDIAL is indicated, and should be continuously administered during entire gestation.

CHAS. CLAY, M. R. C. S., Manor House, Dewsbury, England, says:—I find Aletris Cordial (Rio) is of great service in threatened miscarriage.

FRANCIS E. CANE, L. R. C. S., &c., Leeds, England, says:—I have tried the Aletris Cordial (Rio) in two cases of long standing dysmenorrhea, with excellent results. One of these patients has spent a week in bed every month for two years. After all the usual remedies, I put her on Aletris Cordial, and for the last two periods she has been out and about all the time.

L. M. WATSON, M. D., Delhi, Ills., says:—I have used Aletris Cordial (Rio) in cases of dysmenorrhea, suppressed menses and threatened miscarriage, and also, combined with Celerina, as a tonic after confinement, with the happiest results, and now I am using it on a case of leucorrhea, with injections of S. H. Kennedy's Extract of Pinus Canadensis, and it is acting like a charm.

P. H. OWEN, M. D., Morganville, Ala., says:—I have prescribed Aletris Cordial (Rio) in several cases with the most satisfactory results, and regard it as the best uterine tonic I have met with in a professional experience of over twenty-five years. In cases of threatened miscarriage it acts like a charm. Would recommend its continuous administration in all cases when there is any indication of miscarriage.

Dr. W. BERTHELOT, Santander, Spain, says:—I have tried the Aletris Cordial (Rio), and it has seemed to me to be useful, especially in cases of dysmenorrhea.

Dr. RASQUINET, Jupile, near Liege, Belgium, says:—I tried Aletris Cordial (Rio) in the case of a woman who had had several miscarriages at the end of five months, and who is now again pregnant, having reached the seventh month, thanks to Aletris Cordial.

R. REECE, M. R. C. S., Walton-on-Thames, England, says:—Aletris Cordial (Rio) in painful menstruation is most valuable. A wife of a minister suffered much, and had had three miscarriages I prescribed Aletris Cordial. She has for the first time, gone her full time, and was safely confined with a male child.

J. T. COLLIER, M. D., Brooks, Me., says:—I have used your Aletris Cordial (Rio) in cases of females at the menopause. Consider it one of the finest remedies for these cases.

Dr. GORDILLON, St. Amand, France, says: I have tried the Aletris Cordial (Rio) in a case of dysmenorrhea. The result I obtained from the use of your preparation was excellent, better than I had obtained in the same patient by prescribing the usual remedies employed in such cases.

W. F. TOOMBS, M. D., Morrillton, Ark., says:—I have used a great deal of your Aletris Cordial (Rio) and I find it all you claim for it in amenorrhea, dysmenorrhea, metritis, leucorrhea; I don't think it has an equal. I have used it in two cases of threatened miscarriage and the trouble was obviated. For a general Uterine Tonic I know of nothing superior.

R. D. PATTERSON, L. R. C. S. &c., Medical Officer, Caledon Dispensary, Co. Tyrone, Ireland, says:—I have very great pleasure in testifying to the very high opinion I hold of Aletris Cordial (Rio) in threatened miscarriage.

SPORTING AND ATHLETIC GOODS OF EVERY DESCRIPTION.

No Chemicals.

W. BAKER & CO.'S Breakfast Cocoa

Is Absolutely Pure, and it is Soluble.

To increase the solubility of the powdered cocoa, various expedients are employed, most of them being based upon the action of some alkali, potash, soda or even ammonia. Cocoa which has been prepared by one of these chemical processes, can usually be recognized at once by the distinct alkaline reaction of the infusion in water.

W. Baker & Co.'s Breakfast Cocoa

is manufactured from the first stage to the last by perfect mechanical processes, **no chemical being used in its preparation.** By one of the most ingenious of these mechanical processes the greatest degree of fineness is secured without the sacrifice of the attractive and beautiful red color which is characteristic of an absolutely pure and natural cocoa.

BOUDAULT'S PEPSINE

The only Pepsine used in the Hospitals of Paris for the last Thirty Years.

Unlike the various substitutes which, in most cases, are but unscientific or incompatible compounds, forced upon the Medical Profession as aids to digestion by extensive advertising, but which, when submitted to the proper tests, are found to be useless as digestive agents, Pepsine is constantly gaining in the esteem of the careful practitioner.

Since the introduction of Pepsine by Boudault and Corvisart in 1854, the original BOUDAULT'S PEPSINE HAS BEEN AT ALL TIMES CONSIDERED THE BEST, as is attested by the awards it has received at the Expositions of 1867, 1868, 187 1873, in 1876 at the Centennial Exposition of Philadelphia, and in 1878 at the Paris Exposition.

The most reliable tests, carefully applied, will satisfy everyone that BOUDAULT'S PEPSINE HAS A MUCH HIGHER DIGESTIVE POWER than the best Pepsines now before the Profession, and is therefore especially worthy of their attention.

BOUDAULT'S PEPSINE is prepared in the form of Pepsine Acid and Pepsine Neutral. It is sold in bottles of one ounce, with a measure containing exactly five grains; also in bottles of four, eight, and sixteen ounces for dispensing.

BOUDAULT'S WINE OF PEPSINE

FORMULA OF DR. CORVISART.

The taste of Pepsine being perfectly disguised in this Wine, it may be recommended to persons who have difficulty in taking Pepsine in the form of Powder. This Wine is tested so that a tablespoonful of it is equal in digestive power to ten grains of Boudault's Pepsine in powder. Sold only in bottles of eight ounces.

TANRET'S PELLETIERINE

For the Treatment of Tape-Worm (Tænia Solium).

This New Tænifuge, the Active Alkaloid of Pomegranate Bark, has of late come into extensive use in France for the treatment of Tape-Worm (Tænia Solium). The results of numerous experiments with it at the Marine Hospitals of Toulon, St. Mandrier, etc., and in the Hospitals of Paris, St. Antoine, La Charité, Necker Beaujon, etc., have all been most satisfactory. Doctor Dujardin Beaumetz, Member of the Academy of Medicine, and Professor Laboulbene, in their report to the Society of Therapeutics, have given it their unqualified approval, after the most searching experiments. This preparation is pleasant to administer, and, if certain preliminaries are observed, success will be insured.

Sold only in bottles containing one dose.

DUCRO'S ALIMENTARY ELIXIR

A Combination uniting the properties of Alcoholic Stimulants and Raw Meat.

This preparation, which has been used with great success in the hospitals of Paris since 1868, is adapted to the treatment o all diseases requiring administration, in a small volume, of a tonic able to stimulate and support the vital forces, as *Pulmonar Phthisis, Depression and Nervous Debility, Adynamia, Malarious Cachexia, etc.*

Prepared by EMILE DURIEZ & CO., Successors to DUCRO & CIE, Paris.

KIRKWOOD'S INHALER

This is the only complete, reliable, and effective inhaler in use, arranged for the direct application of Muriate of Ammonia and other remedial agents in the state of vapor to the diseased parts of the air-passages in the treatment of catarrh and diseases of the throat and lungs. No heat or warm liquids required in its use.

It is entirely different from the various frail, cheap instruments that have been introduced.

KIRKWOOD'S INHALER is accompanied by testimonials of the highest professional character, together with carefully prepared formulas for use.

RETAIL PRICE, COMPLETE, $2.50.

☞ A liberal discount allowed to the trade and profession. For descriptive pamphlet or other information address

P. D. KEYSER, A.M., M.D., Dean, Professor of Ophthalmology.

SAMUEL B. HOWELL, A.M., M.D., Professor of Chemistry.
JOHN V. SHOEMAKER, A.M., M.D., Professor of Materia Medica, Pharmacology, Therapeutics and Clinical Medicine.
E. E. MONTGOMERY, B.S., M.D., Professor of Gynecology.
JAS. M. ANDERS, Ph.D., M.D., Professor of Hygiene and Clinical Diseases of Children; Associate Professor of Physiology

JOHN V. SHOEMAKER, A.M., M.D., Clinical Professor Skin Diseases.

FRANK WOODBURY, A.M., M.D., Honorary Professor of Clinical Medicine.
WM. B. ATKINSON, A.M., M.D. Honorary Professor of Sanitary Science and Paediatrics.

The Regular Session begins September 30th, 1889, and continues until the middle of April. It is preceded by a Preliminary Session of three weeks, and followed by a Spring Session lasting until the middle of June.

Seats are issued in the order of matriculation, and are forfeitable if fees are not paid before November 1st.

Preliminary examination or equivalent degree, and a three years' graded course obligatory. A fourth year voluntary.

Instruction is given by lectures, clinical teaching and practical demonstrations. In the subjects of Anatomy, Pharmacy, Chemistry, Histology and Pathology the usual methods of instruction are largely supplemented by laboratory work.

Examinations are held at the close of each Regular Session upon the studies of the term. Although the degree of Doctor of Medicine is conferred at the end of the third year, a fourth year is earnestly recommended, at the end of which the degree of Doctor of Medicine *cum laude* is given.

FEES.

Matriculation, $5: first and second years, each, $100; third year (no graduation fee), $100; fourth year, free to those who have attended three sessions in this school, to all others, $100.

Extra charges only for material used in the laboratories and dissecting-room.

For further information or announcement, address,

E. E. MONTGOMERY, M.D., Secretary,
Medico-Chirurgical College,
Cherry, below 18th Street, Philadelphia, Penna.

Medical College of Ohio.

Medical Department of the University of Cincinnati.

The Seventy-first Annual Session will begin September 4, 1889, and continue until March 1, 1890.

FEES.—Matriculation Ticket, $5.00; General Lecture Ticket, $75.00; Hospital Ticket, $5.00; Graduation Fee, $25.00.

For circulars, and further information, address
JAMES G. HYNDMAN, M.D., Secretary,
22 West Ninth Street, Cincinnati, Ohio.

WESTERN PENNSYLVANIA MEDICAL COLLEGE

CITY OF PITTSBURGH.

SESSIONS OF 1889—90.

The REGULAR SESSION begins on the last Tuesday of September, and continues six months. During this session, in addition to four Didactic Lectures, two or three hours are daily allotted to Clinical Instruction. Attendance upon two regular courses of lectures is requisite for graduation. A three years' graded course is also provided. The SPRING SESSION embraces recitations, clinical lectures and exercises, and didactic lectures on special subjects; this session begins the second Tuesday in April, and continues ten weeks.

The laboratories are open during the collegiate year for instruction in chemistry, microscopy, practical demonstrations in medical and surgical pathology, and lessons in normal histology. Special importance attaches to "the superior clinical advantages possessed by this College." For particulars, see annual announcement and catalogue, for which, address the Secretary of Faculty, Prof. J. W. J. McKENNAN.

Business correspondence should be addressed to
PROF. W. J. ASDALE, 2107 Penn Avenue, Pittsburgh.

Woman's Medical College
OF BALTIMORE.

S. E. Cor. Druid Hill Ave. and Hoffman St., Baltimore, Md.

THE EIGHTH ANNUAL SESSION WILL BEGIN ON WEDNESDAY, OCTOBER 2d, 1889.

For further information or catalogue, address
RANDOLPH WINSLOW, M.D., Acting Dean,
No. 1, Mount Royal Terrace, Baltimore, Md

Medical Department, State University of Iowa,
at Iowa City, Iowa.

The next Session will begin on September 11, 1889, and continue until March 12, 1890. Attendance upon three courses of lectures, of six months each, is requisite to graduation. The facilities for dissection and clinical study are unsurpassed.

TERM EXPENSES—Lecture Ticket, $20.00; Demonstrator's Ticket, $10.00; Matriculation Ticket, $5.00 (paid but once); Hospital Ticket, $1.00; Examination Fee (for final examination) $25.00. No charge for dissecting material. For further information, address DR. A. C. PETERS, Ast. Sec'y, Iowa City, Iowa.

GENUINE BLAUD'S PILLS.

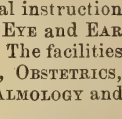
These pills, which have been inserted in the new French Pharmacopœia, have been employed with the greatest success for more than fifty years by most French and foreign physicians, to cure anemia, chlorosis, and all chlorotic affections in which iron is indicated.

Here is the opinion of men most eminent in medical science who have employed them.

"For thirty-five years, in which I have practised medicine, I have recognized the incontestable advantages of BLAUD'S PILLS over all other ferruginous preparations, and I regard them as the best anti-chlorotic."—DR. DOUBLE, *Ex-President of the Academy of Medicine.*

"Of all the ferruginous preparations, which have given good results in the treatment of chlorotic affections, BLAUD'S PILLS appear to us to deserve to hold the first rank."—*Dictionnaire universel de médecine*, Vol. II, p. 99.

These pills, prepared according to the genuine formule of the originator, by his nephew, Aug. Blaud, Pharmacist of the Faculty of Paris, are sold only in bottles of 200 pills and half bottles of 100 pills, at a cost of 5 and 3 francs ($1.00, and seventy-five cents), and never in smaller quantities. *See that his name is stamped on each pill.* **PARIS, 8 RUE PAYENNE, and at every Pharmacy.** (Beware of imitations.)



DETROIT COLLEGE OF MEDICINE.

SESSION 889-90.

Clinical and Practical teaching are made an important feature of this College. Clinical instruction is given daily at HARPER, ST. MARY'S and ST. LUKE'S HOSPITAL, at the COLLEGE, at COLLEGE EYE and EAR INFIRMARY, ST. MARY'S FREE EYE and EAR INFIRMARY, and at the three FREE DISPENSARIES. The facilities offered by this college are unsurpassed for the practical study of MEDICINE, SURGERY, OBSTETRICS, GYNÆCOLOGY, DISEASES OF CHILDREN, GENITO-URINARY, and ORTHOPÆDIC SURGERY, OPHTHALMOLOGY and OTOLOGY, DERMATOLOGY and LARYNGOLOGY.

REGULAR SESSION opens on Wednesday, Sept. 25, and continues six months. During the session, the Professors will take special pains to examine the Students upon the subjects of the previous lectures.

SPRING SESSION begins April 2d, 1890; and closes June 11th.

FEES.—Matriculation fee, $5; Fees for Regular Session, $50; Spring Session, $10, to those who attend the regular term—to all others, $25; Hospital Fee, $10; Graduation Fee, $30; Perpetual Ticket, $100.

For further particulars, and for College Circular, apply to

H. O. WALKER, M.D., Secretary,
33 Lafayette Ave., Detroit, Mich.

UNIVERSITY OF PENNSYLVANIA.—Medical Department.

The 124TH ANNUAL WINTER SESSION will begin Tuesday, October 1st, 1889, at 12 M., and continue until May 1st, 1890.

The PRELIMINARY SESSION begins September 18th, 1889.

The curriculum is graded and three annual winter sessions are required. Practical instruction, including laboratory work in Chemistry, Histology, Osteology and Pathology, with Bedside Instruction in Medicine, Surgery and Gynecology are a part of the regular course and without additional expense.

FACULTY.

JOSEPH LEIDY, M.D., LL.D., Professor of Anatomy.
D. HAYES AGNEW, M.D., LL.D., Honorary Professor of Clinical Surgery.
WILLIAM PEPPER, M.D., LL.D., Professor of Theory and Practice of Medicine, and of Clinical Medicine.
WILLIAM GOODELL, M.D., Professor of Gynecology.
JAMES TYSON, M.D. Professor of Clinical Medicine.
HORATIO C. WOOD, M.D., LL.D., Professor of Materia Medica, Pharmacy and General Therapeutics.
THEODORE G. WORMLEY, M.D., LL.D., Professor of Chemistry and Toxicology.
JOHN ASHHURST, JR., M.D., Professor of Surgery and of Clinical Surgery.
EDWARD T. REICHERT, M.D., Professor of Physiology.

BUFFALO LITHIA WATER

IN THE TREATMENT OF

ALBUMINURIA, WHETHER OF BRIGHT'S DISEASE, PREGNANCY, OR SCARLET FEVER.

Dr. WM. B. TOWLES, Professor of Anatomy and Materia Medica in the Medical Department of the University of Virginia.

"BUFFALO LITHIA WATER, No. 2, belongs to the ALKALINE or, *perhaps, to the* ALKALINE-SALINE Class, *for it has proved far more efficacious in many diseased conditions than any of the simple* ALKALINE *waters.*

. . . . . .

"*Its effects are marked in causing a disappearance of* ALBUMEN *from the Urine.* In a single case of BRIGHT'S DISEASE OF THE KIDNEYS I witnessed *decided beneficial results from its use, and from its action in this case I should have great confidence in it as a remedy in certain stages of the disease.*"

Dr. GRAEME M. HAMMOND, of New York, Professor of Diseases of the Mind and Nervous System in the New York Post-Graduate Medical School and Hospital.

"In *all* cases of BRIGHT'S DISEASE of the KIDNEYS I have found BUFFALO LITHIA WATER *of the greatest service in increasing the quantity of urine and in eliminating the* ALBUMEN."

Dr. GEORGE W. MILTENBERGER, Professor of Obstetrics, University of Maryland,

Before the Medical and Chirurgical Faculty of the State of Maryland, recommended BUFFALO LITHIA WATER as an ALKALINE Diuretic in ALBUMINURIA of PREGNANCY.—See *Trans. Faculty of State of Maryland*, 1886.

Dr. WM. H. DOUGHTY, Professor of Materia Medica and Therapeutics, Medical College of Georgia; Member of American Medical Association, etc.

"Over the NAUSEA AND VOMITING OF PREGNANCY, PARTICULARLY IN THE LATTER MONTHS, WHERE URÆMIC CONDITIONS are possibly established, and in PUERPERAL CONVULSIONS, URÆMIA CO-EXISTING, BUFFALO LITHIA WATER often exerts *marked control.*"

Dr. CALEB WINSLOW, 23 McCulloh Street, Baltimore, Member of the Medical and Chirurgical Faculty of Maryland.

"I have found the BUFFALO LITHIA WATER, Spring No. 2, of marked service in relieving the *Nausea of Pregnant Women.* I frequently resort to it at intervals *during the whole course of Pregnancy.* Being *antacid, laxative, diuretic, and tonic, it seems well adapted to relieve the disturbances usually attendant upon Gestation, and I have no doubt its free use might remove* URÆMIC POISON, *and prevent Convulsions produced thereby.*"

Dr. JOS. HOLT, New Orleans, President Board of Health, State of Louisiana.

"I have prescribed BUFFALO LITHIA WATER freely in affections of the *Kidneys* and *Urinary* passages, particularly in GOUTY *subjects*, in ALBUMINURIA, and in irritable conditions of the *Bladder* and *Urethra* in *females.* The results have been such as to satisfy me *of the extraordinary value of this Water in a large class of cases usually most difficult to treat.*"

Dr. JAMES B. McCAW, Professor of the Practice of Medicine in the Virginia Medical College.

[Extract from the Proceedings of the Richmond Academy of Medicine, October 15, 1878.]

"Dr. McCaw also spoke of the great value of BUFFALO LITHIA WATER in ALBUMINURIA of *Scarlet Fever* and in ALBUMINURIA of *Pregnant Women.*"

Dr. J. T. DAVIDSON, New Orleans, La., ex-President New Orleans Surgical and Medical Association.

"I have for several years prescribed BUFFALO LITHIA WATER, Spring No. 2, in all cases of *Scarlet Fever*, directing it to be drunk *ad libitum, with the effect of relieving all traces of* ALBUMEN *in the urine*, and have found it equally efficacious in renal diseases requiring the use of alkaline water."

Dr. G. W. SEMPLE, Hampton, Va., President Medical Society of Virginia.

"In SCARLET FEVER I have known BUFFALO LITHIA WATER *restore a healthy and abundant secretion of Urine, when it was highly charged with* ALBUMEN *and the secretion almost suppressed.*"

Dr. MARTIN L. JAMES, of Richmond, Va., Professor of Materia Medica and Therapeutics, Medical Society of Virginia.

[Proceedings of the Richmond. Virginia, Academy of Medicine, December 16, 1880.]

"The President of the Academy, Dr. M. L. James, reported a case of *Congestion* of the *Kidneys* in a lady eight months advanced in *Pregnancy, attended by marked Œdema*, both over the extremities and surface, and by URÆMIC POISONING *to such an extent as very seriously impaired the vision of the patient*, relieved by the free use of this Water for three weeks.

"Other remedies, he stated, were used in these cases, *but the favorable results seemed clearly attributable to the action of the Water.*"

Dr. HARVEY L. BYRD, of Baltimore, President and Professor of Obsetrics and Diseases of Women and Children in the Baltimore Medical College, formerly Professor of Practical Medicine, etc.

"I have prescribed BUFFALO LITHIA WATER with the most satisfactory results, both as a *remedy* and *prophylactic* in the *Parturient* or *Pregnant Puerperal Eclampsia* or *Convulsions; and I may say that I know of no remedy of equal efficacy with the Water of Spring No. 2 in Sequelæ of Scarlatina.*

"It has an *ascertained value* in BRIGHT'S DISEASE. *A knowledge of its action in that disease thus far would seem* to warrant the belief that it would, in many instances, *at least in its early stages, arrest it entirely, and in its more advanced stage prove a decided comfort and palliative.*

Water in cases of one dozen half-gallon bottles, $5.00 per case at the Springs.

The Curd of Cow's Milk
Made as Soft and Digestible as that of Woman's Milk.

"From experiments which I have recently made — and my thanks are due to Prof. Salisbury of the Woman's Medical College, for assistance — it seems that the claim which is made by the advocates of the MELLIN'S FOOD is true, and that the addition of this food to cow's milk does cause it to break up in very small, flaky curds."— *Dr. Chas. Warrington Earle, Professor of Diseases of Children, Woman's Medical College, Professor of Obstetrics, College Physicians and Surgeons, Chicago, in his paper on Infant Feeding, before the American Medical Association, May, 1888.*

Any physician having a case in which he desires to test MELLIN'S FOOD can obtain a sample sufficient for trial, free of all expense, by application.

ADDRESS:

Publisher **Medical and Surgical Reporter,**

P.O. Box 843. PHILADELPHIA, PA.

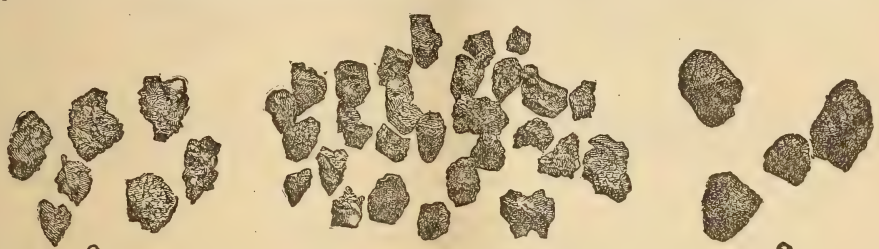
Buffalo Lithia Water

In the TREATMENT OF URINARY DEPOSIT.

Case of Dr. B. J. WEISTLING, of Middleton, Pa., stated by himself.

"Experience in its use in **STONE in the BLADDER** in my own person enables me to attest the efficacy of the **BUFFALO LITHIA WATER** in this painful malady. After having been long subjected to sufferings, the intensity of which cannot be described, I have, under the influence of this Water, passed an ounce of **CALCULI (URIC ACID)**, some of which weighed as much as four grains, affording inexpressible relief and leaving me in a condition of comparative ease and comfort.

"On one occasion I passed thirty-five **CALCULI** in forty-eight hours. The appearance of these **CALCULOUS NUCLEI** indicates unmistakably, I think, that they were all *component particles of one large* **CALCULUS** *destroyed by the action of the Water, by means of solution and disintegration.* At my advanced period of life (I am seventy-seven years and six months of age), and in my feeble general health, a surgical operation was not to be thought of, and the Water seems to have accomplished all that such an operation, if successful, could have done."



[The above plate is from a photograph, and represents the exact size and shape of some of the Calculi passed by Dr. Weistling. They were preserved by his son, Dr. J. Weir Weistling.]

Case stated by Dr. G. HALSTED BOYLAND, late Professor of Surgery, Baltimore Medical College, Member American Medical Association.

"The case of Mr. C., which came under my observation as Resident Physician at the Springs during the season of 1884, affords undoubted evidence that Buffalo Lithia Water is a **SOLVENT** *for Urinary Deposit*, commonly known as **STONE in the BLADDER.** He was operated upon for **STONE**, the operation affording but partial and temporary relief. A year afterward he visited the **BUFFALO LITHIA SPRINGS**, at the same time passing small quantities of a *Urinary Deposit*, of the **TRIPLE PHOSPHATE of AMMONIA** and **MAGNESIA VARIETY**, and his sufferings such as required that he should be kept constantly under the influence of opiates. In some eight weeks the solvent properties of the Water *were evident in the diminished consistency of the deposit, the increased quantity discharged, and by its change from Concrete Lumps to fine Sand*, which he discharged to the amount of *Four Ounces.* After a time, however, the quantity gradually diminished, and finally ceased, and he left the Springs *with the deposit dissolved* and *washed out of the system*, and the *Diathesis fons et origi morbi* altered. There had been a disappearance of the attending distressing symptoms, and great improvement in his general condition."

Dr. MARTIN L. JAMES, of Richmond, Va., Professor of Materia Medica and Therapeutics, Medical Society of Virginia.

[Proceedings of the Richmond, Virginia, Academy of Medicine, December 16, 1880.]

"The President of the Academy, Dr. M. L. James, reported three cases of marked **URIC ACID DIATHESIS** successfully treated by the Water of Spring No. 2 of the **BUFFALO LITHIA SPRINGS** of Virginia. In one of these patients there were, as a result of this Diathesis, **SANDY DEPOSITS** in the *Urine, Inflammation of the Kidneys, Irritability of the Bladder, and Hæmaturia*, and, finally, the passage of a **CALCULUS** of the size of a cherry, formed on a blood-clot as a nucleus. In another case there were frequent attacks of **NEPHRITIC COLIC**, attended by **SANDY DEPOSITIONS** in the urine. After the free use of this Water in these cases, no further manifestations of the disorder occurred."

Dr. HENRY M. WILSON, of Baltimore, ex-President Medical and Chirurgical Faculty of Maryland.

"My experience in the use of the **BUFFALO LITHIA WATER** has not been large, *but it is of such a positive character that I do not hesitate to express my preference for it, as a* **DIURETIC** in **URINARY CALCULI**, *over all other waters that I have ever used.*"

Water in cases of one dozen half-gallon bottles, $5 per case, at the Springs.

THOMAS F. GOODE, Proprietor,

BUFFALO LITHIA SPRINGS, VIRGINIA.

THE NEW HYPNOTIC
SULFONAL-BAYER.

SULFONAL was discovered by Prof. Eugen A. Baumann, of Freiburg University, and was first prepared by the Farbenfabriken vorm. Friedr. Bayer & Co., Elberfeld.

SULFONAL (Diæthylsulfondimethylmethan) is in the form of colorless prisms, odorless, and tasteless, melting at 125.5° C. (258° F.) and has the composition $(C H_3)_2=C=(C_2 H_5 SO_2)_2$. It is slightly soluble in cold water, but easily soluble in hot water or alcohol.

SULFONAL was first examined as to its physiological and pathological effects by Prof. A. Kast, of Freiburg University, and its hypnotic action was discovered and studied by him.

Since then SULFONAL has been the subject of numerous trials and experiments by many eminent and experienced physicians. Their testimony is unanimously favorable, and the conclusions reached by them are as follows:

SULFONAL is a prompt and reliable hypnotic, which in proper doses, produces quiet, natural sleep, lasting a number of hours.

SULFONAL has no unfavorable effects on the heart and the circulation, nor on the temperature, the pulse, or the respiration.

SULFONAL produces no disagreeable secondary symptoms; the patients with very few exceptions awake from their sleep feeling strong and greatly refreshed.

SULFONAL does not interfere with the process of digestion.

SULFONAL is a hypnotic, and not a narcotic; it acts by giving rest to the cells of the cerebral cortex, thereby causing sleep.

SULFONAL does not create an unconquerable desire for its repeated use; there is no danger of a SULFONAL-habit. Neither is it necessary to increase the dose after long-continued use.

SULFONAL is best administered at supper-time, dissolved in hot liquids, *e. g.*, a bowl of soup or broth, a cup of milk, tea, coffee, cocoa, etc.

These points will be found to be fully exhibited in the series of contributions contained in our pamphlet, which will be mailed on application.

SULFONAL-BAYER is supplied by us in half-ounce and one-ounce vials.

We prepare 5-grain and 15-grain Tablets of Sulfonal-Bayer. The tablet form is admirably adapted to the purpose of administering this drug, as when they are placed in the liquids, they disintegrate and are thus received into the system.

We also put up Sulfonal-Bayer in the form of our Soluble Pills, containing five grains each.

THE NEW ANTIPYRETIC
PHENACETINE-BAYER.

Phenacetine-Bayer (Para-Acetphenetidine) is a white, glossy, crystalline powder, perfectly tasteless, melting at 135° C.=307° F and has the composition $C_6 H_4 < {}^{O.C_2H_5}_{NH(CO-CH_3)}$.

It is slightly soluble in water, a little more soluble in glycerine, but most freely in alcohol.

Phenacetine-Bayer was first prepared by the Farbenfabriken, formerly Friedr. Bayer & Co., Elberfeld, and is of absolute purity and uniform quality.

Summarizing the superiority of Phenacetine-Bayer over other antipyretics and antineuralgics, the following conclusions are formed:

1. ***Phenacetine-Bayer is an efficacious antipyretic.***
2. ***It does not develop any disagreeable or noxious after-effects.***
3. ***The dose required is half that of Antipyrine.***
4. ***It is perfectly tasteless.***
5. ***On account of its innocuousness and tastelessness, it is a valuable antipyretic both in adults and in children.***
6. ***Phenacetine-Bayer is an important antineuralgic; its effect is more energetic than that of Antipyrine and does not cause lassitude or any other disagreeble symptoms.***

Our pamphlet on Phenacetine-Bayer, containing the valuable testimony of eminent physicians will be mailed on application.

We offer Phenacetine-Bayer in one-ounce vials, or in the form of our Soluble Pills of the strength of two and four grains to each pill.

RABUTEAU'S DRAGEES OF IRON

Laureate of the Institute of France.—Prize in Therapeutics.

The studies made by the Physicians of the Hospitals have demonstrated that the **Genuine Dragees of Iron of Rabuteau** are superior to all other preparations of Iron in cases of *Chlorosis, Anæmia, Leucorrhœa, Debility, Exhaustion, Convalescence, Weakness of Children*, and the maladies caused by the Impoverishment and Alteration of the blood after periods of fatigue, watching, and excesses of any kind.

TAKE 4 TO 6 DRAGEES DAILY.

Rabuteau's Elixir of Iron is recommended to those persons who may be unable to swallow the Dragees. Dose —*A small wineglassful with meals.*

Rabuteau's Syrup of Iron is specially designed for children. Chalybeate medication, by means of **Rabuteau's Iron,** is the most economical and the most rational known to therapeutics.

No constipation, no diarrhœa, complete assimilation.

Take only the GENUINE IRON OF RABUTEAU of

CLIN & CO., Paris.

SOLUTION OF

THE SALICYLATE OF SODA OF DOCTOR CLIN.

Laureate of the Paris Faculty of Medicine (MONTYON PRIZE).

Dr. Clin's Solution, always identical in its composition, and of an agreeable taste, permits the easy administration of *pure Salicylate of Soda*, and the variation of the dose in accordance with the indications presented.

"The *Salicylate of Soda* used by **Clin** is of perfect purity, "and is prepared with the greatest care; it is a medicament "in which we may have every confidence."

—*Paris Society of Medicine, Meeting of Feb. 8th, 1879.*

Clin's Solution, very exactly mixed, contains: 2 grammes of *Salicylate of Soda* per tablespoonful, 50 centigrammes of *Salicylate of Soda* per teaspoonful.

CLIN & CO.,—Paris.

GRAND NATIONAL PRIZE OF 16,600 FRANCS,

QUINA-LAROCHE

This meritorious **Elixir, QUINA-LAROCHE,** is prepared from the **three** Cinchonas; it is an agreeable and doubtless highly efficacious remedy.

—*The Lancet.*

VINOUS ELIXIR,

A STIMULATING RESTORATIVE

—AND—

ANTI-FEBRILE TONIC.

QUINA-LAROCHE under the form of a vinous **Elixir** contains the totality of the numerous principles of the **three** Cinchona barks. It is a preparation which renders great services to Therapeutics.—Extract of the *Gazette des Hôpitaux*, Paris.

FAR SUPERIOR TO ALL ORDINARY CINCHONA WINES.

LAROCHE'S QUINA, tried by the Academy of Medicine of Paris, is a specially prepared COMPOUND EXTRACT of Quinquina, a careful analysis, confirmed by experience, has shown that most of the wines and syrups hitherto used have not contained all the properties of this precious bark, of these some, although beneficial, are altogether lost, while many preparations contain but half the properties of the bark in varying proportions.

MR. LAROCHE, by his peculiar method, has succeeded in extracting all the active principles of the quinquina, combining these with *Catalan Wine* forming an Elixir free from the disagreeable bitterness of other similar preparations. Practitioners have found triple advantages in the use of this Elixir, it is a *strong tonic*, is easily administered, and perfectly harmless, being free from the unpleasant effects of Quinine.

THE FERRUGINOUS QUINA-LAROCHE is the invigorating tonic *par excellence*, having the advantage of being easily assimilated by the gastric juice; without, in any way, deranging the action of the digestive organs, proving itself to be a most efficacious remedy in cases of impoverishment of the blood, ANÆMIA, CHLOROSIS, INTESTINAL HÆMORRHAGE, CASTRALGIA, EXHAUSTION, ETC., ETC.

PARIS.—22 RUE DROUOT.—PARIS.

ANTISEPTIC DRAINAGE TUBES.—Glass.

These Tubes have large holes, one-half inch apart, arranged alternately on opposite sides.
They are carefully finished, especial care being taken to make them smooth.
In addition to the drainage-holes, each tube has at one end two smaller holes for the insertion of Safety-Pin, through which it is prevented slipping into the wound.

FURNISHED IN SEVEN SIZES.

No. 1,	$1.25 per doz.	No. 4,	$1 55 per doz.
No. 2,	1.25 "	No. 5,	1.70 "
No. 3,	1.40 "	No. 6,	1.90 "
	No. 7, $2.10 per dozen.		

RAW CAT-GUT. I put this up in coils of 10 feet, four difierent sizes, Nos. 1. 2, 3. 4 (4 is thickest). Nos. 2 and 3 are the most useful sizes. **No. 1 Coil, 10 Cents; No. 2 Coil, 12 Cents; No. 3 Coil, 14 Cents; No. 4 Coil, 16 Cents.** Full directions with each coil for making it absolutely aseptic.

No. 7 SOUTH ELEVENTH STREET, PHILADELPHIA.

BROMIDIA

THE HYPNOTIC.

FORMULA.—

Every fluid drachm contains 15 grains EACH of Pure Chloral Hydrat. and purified Brom. Pot., and one-eighth grain EACH of gen. imp. ext. Cannabis Ind. and Hyoscyam.

DOSE.—

One-half to one fluid drachm in WATER or SYRUP every hour, until sleep is produced.

INDICATIONS.—

Sleeplessness, Nervousness, Neuralgia, Headache, Convulsions, Colic, Mania, Epilepsy, Irritability, etc. In the restlessness and delirium of fevers it is absolutely invaluable.

IT DOES NOT LOCK UP THE SECRETIONS.

PAPINE

THE ANODYNE.

Papine is the Anodyne or pain-relieving principle of Opium, the Narcotic and Convulsive Elements being eliminated. It has less tendency to cause Nausea, Vomiting, Constipation, Etc.

INDICATIONS.—

Same as Opium or Morphia.

DOSE.—

(ONE FLUID DRACHM)—represents the Anodyne principle of one-eighth grain of Morphia.

IODIA

The Alterative and Uterine Tonic.

FORMULA.—

Iodia is a combination of active principles obtained from the Green Roots of Stillingia, Helonias, Saxifraga, Menispermum, and Aromatics. Each fluid drachm also contains five grains Iod. Potas., and three grains Phos. Iron.

DOSE.—

One or two fluid drachms (more or less as indicated) three times a day before meals.

INDICATIONS.—

Syphilitic, Scrofulous and Cutaneous Diseases, Dysmenorrhea, Menorrhagia, Leucorrhea, Amenorrhea, Impaired Vitality, Habitual Abortions, and General Uterine Debility.

A Peerless Chemico-Physiological Food and Restorative

Crystalline Phosphate

A

TISSUE FOOD

PHOSPHATIC FOOD PRODUCTS TRADE MARK

Contains all essential inorganic components of the tissues in a semi-solid, easily soluble, crystalline mass,

COMPOSED OF

ACID PHOSPHATE OF CALCIUM.

WITH

Acid Phosphate of Magnesium,
" " " Iron,
" " " Sodium,
" " " Potassium,

Chloride of Potassium,
" " Sodium
Sulphate of Potassium,
and Phosphoric acid.

INDICATIONS:

STOMACH DISORDERS, such as Indigestion, Flatulence Gastric Catarrh, and Poor Appetite, Constipation, etc.

WRONGS OF NUTRITION, as in Scrofula, Rickets, Caries, Marasmus, Delayed Union of Fractures, Necrosis of Tissue, Difficult or Delayed Dentition and Development, etc.

NERVOUS AND GENERAL DEBILITY AND SLEEPLESSNESS, as from Sexual Excess, Venerial Disease, Childbearing, Nursing, Loss of Blood or other fluids, Menstrual and other Diseases of Women, abuse of Alcohol, Tobacco and Narcotics, Protracted Illness, etc.

DEBILITY AND DYSPEPSIA.—*Your preparation of* **Crystalline Phosphate,** *I have found to be very excellent in cases of Debility from Nerve Exhaustion. It is a good auxilliary in Gastric and Dyspeptic Troubles, and from my experience I regard it as a reliable preparation.* T. GRISWOLD COMSTOCK, A. M., M. D., PH. D., ST. LOUIS, MO.

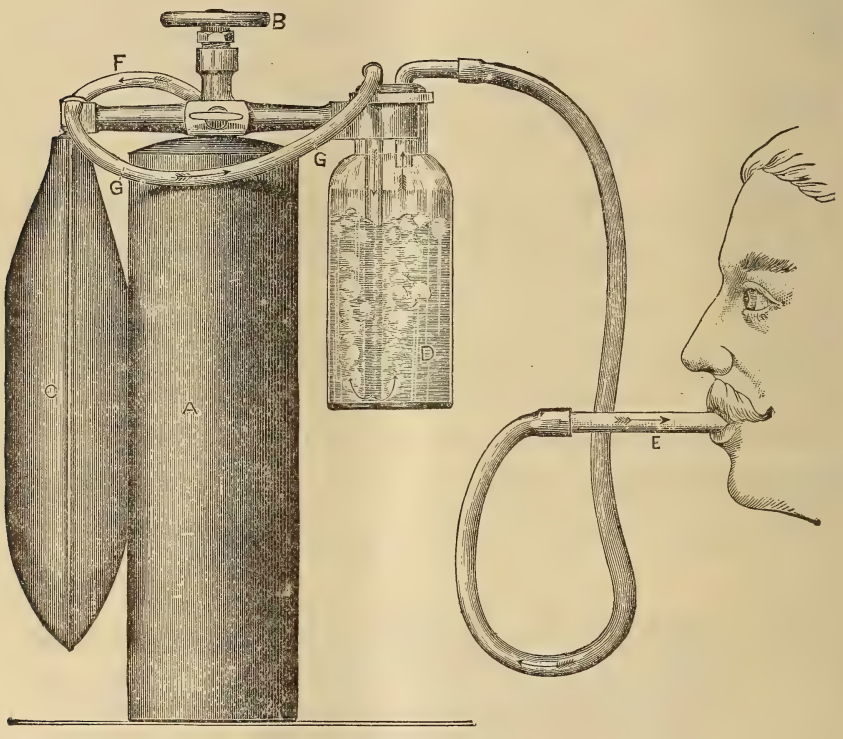
Established 1866. **Philadelphia.**

INHALATION APPARATUS

FOR

THE THERAPEUTIC ADMINISTRATION OF OXYGEN.



In the treatment of lung troubles by Oxygen its exhibition by inhalation is preferred. The apparatus herewith shown is a modification of the Nitrous Oxide apparatus which we have supplied for many years. It is made in the best manner throughout, and is the outcome of years of experience in the manufacture of gas apparatus. It will be found to meet all the requirements.

We supply the gas in two sizes of cylinders, containing respectively forty and one hundred gallons, either pure Oxygen, or a mixture of Oxygen and Nitrous Oxide in definite proportions of 20 per cent., and forty per cent. of Nitrous Oxide.

Whether pure or mixed the gas is sold at the uniform price of 5 cents a gallon. The cost of the cylinders will be refunded on their return empty with the valves in good condition. Full description of Inhalation and Enema apparatuses with directions for use accompany each apparatus, or will be supplied on application.

PRICES.

Inhalation Apparatus	$5.00
Cylinder, 40 gallons' capacity	6.00
40 gallons Gas, either pure Oxygen or mixed Oxygen and Nitrous Oxide	2.00
Complete Apparatus, Cylinder, and 40 gallons Gas	$13.00
Inhalation Apparatus	$5.00
Cylinder, 100 gallons' capacity	15.00
100 gallons Gas, either pure or mixed	5.00
Complete Apparatus, Cylinder, and 100 gallons Gas	$25.00

THE S. S. WHITE DENTAL MFG. CO.,

PHILADELPHIA, NEW YORK, BOSTON, CHICAGO, BROOKLYN.

THE BEST ANTISEPTIC
FOR BOTH INTERNAL AND EXTERNAL USE.

ANTISEPTIC, PROPHYLACTIC, DEODORANT.

LISTERINE

NON-TOXIC, NON-IRRITANT, NON-ESCHAROTIC.

FORMULA—Listerine is the essential antiseptic constituent of Thyme, Eucalyptus, Baptisia, Gaultheria and Mentha Arvensis, in combination. Each fluid drachm also contains two grains of refined and purified Benzo-boracic Acid.

DOSE—Internally: One teaspoonful three or more times a day (as indicated) either full strength, or diluted, as necessary for varied conditions.

LISTERINE is a well-proven antiseptic agent—an antizymotic—especially adapted to internal use, and to make and maintain surgical cleanliness—asepsis—in the treatment of all parts of the human body, whether by spray, irrigation, atomization, or simple local application, and therefore characterized by its particular adaptability to the field of

PREVENTIVE MEDICINE—INDIVIDUAL PROPHYLAXIS.

Diseases of the Uric Acid Diathesis.

LAMBERT'S

LITHIATED HYDRANGEA

KIDNEY ALTERATIVE—ANTI-LITHIC.

FORMULA—Each fluid drachm of "Lithiated Hydrangea" represents thirty grains of FRESH HYDRANGEA and three grains of CHEMICALLY PURE Benzo-Salicylate of Lithia. Prepared by our improved process of osmosis, it is INVARIABLY of DEFINITE and UNIFORM therapeutic strength, and hence can be depended upon in clinical practice.

DOSE—One or two teaspoonfuls four times a day (preferably between meals).

Urinary Calculus, Gout, Rheumatism, Bright's Disease, Diabetes, Cystitis, Hæmaturia Albuminuria, and Vesical irritations generally.

We have much valuable literature upon { GENERAL ANTISEPTIC TREATMENT, LITHEMIA, DIABETES, CYSTITIS, ETC. } To forward to Physicians upon request:

21 Park Place N.Y.

Geo Hamlin Prest. Chas Roome Parmele Treas.

GENTLEMEN:

The Case of your wines sent me for analysis by Dr. A. L. Hummel, of the "Annals of Hygiene," containing specimens of your La Rosa Zinfandel, Mataro, Riesling, Royal Tokay, and Royal Grape Brandy, has been duly received.

I have examined them for the common contaminants of wine; to wit:
Sulphurous acid and sulphites, salicylic acid, fuchsin, lead salts, etc., none of which I found present therein.

I have also determined their alcoholic strength, extractives, and ashes, and found them to correspond strictly in this respect with the standard of pure and natural wines, which cannot be said of many of the imported wines.

As a native of a wine-producing country, I consider myself somewhat of a judge of wines, and regard your products as comparing more than favorably with most of the wines from abroad which are sold at higher prices, so much so that I enclose within my order for fifty bottles of La Rosa Zinfandel, which I expect to use hereafter exclusively at my table.

Very Respectfully,

L. WOLFF, M.D.,
Demonstrator of Chemistry, Jefferson Medical College.

THE SUSTAINED SUPREMACY

OF

Fairchild's Pepsin,

In ACTIVITY, PERMANENCE and GENERAL EXCELLENCE

Has won for this product a wide use and recognition in all the principal markets of the world.

We guarantee it to be unchangeable, to maintain its activity and quality under all ordinary commercial conditions; it is therefore, by far the most available for the dispensing counter, as well as in the manufacture of every form of pepsin preparation.

Under exactly parallel conditions, with any proper percentage of acidity and with any proportion of such acidulated water to the albumen, Fairchild's pepsin is positively superior to any pepsin known.

It will, under absolutely comparative conditions, grain for grain, digest more albumen than any other pepsin made.

We will be pleased to send samples to any physician who may wish to ascertain for himself the relative activity of Fairchild's pepsin, or to submit it to any practical trial.

Prices and complete information upon application.

FAIRCHILD BROS. & FOSTER,

New York. Chicago. London.

The Curd of Cow's Milk Made as Soft and Digestible as that of Woman's Milk.

"From experiments which I have recently made — and my thanks are due to Prof. Salisbury of the Woman's Medical College, for assistance — it seems that the claim which is made by the advocates of the MELLIN'S FOOD is true, and that the addition of this food to cow's milk does cause it to break up in very small, flaky curds."— *Dr. Chas. Warrington Earle, Professor of Diseases of Children, Woman's Medical College, Professor of Obstetrics, College Physicians and Surgeons, Chicago, in his paper on Infant Feeding, before the American Medical Association, May, 1888.*

Any physician having a case in which he desires to test MELLIN'S FOOD can obtain a sample sufficient for trial, free of all expense, by application.

Doliber-Goodale Co., Boston, Mass.

"SECURUS JUDICAT ORBIS TERRARUM."

THE BEST NATURAL APERIENT.

THE APOLLINARIS COMPANY, LIMITED, London, beg to announce that, as numerous APERIENT WATERS are offered to the public under names of which the word "Hunyadi" forms part, they have now adopted an additional Label comprising their Registered Trade Mark of selection, which consists of

A RED DIAMOND.

This Label will henceforth also serve to distinguish the HUNGARIAN APERIENT WATER SOLD BY THE COMPANY from all other Aperient Waters.

DEMAND THE 
DIAMOND MARK.

And insist upon receiving the HUNGARIAN APERIENT WATER of the APOLLINARIS COMPANY, LIMITED, London.

THE VALUE OF NUTRITION IN DISEASE.

All physicians who have ever used Murdock's Liquid Food and Suppositories recognize their value over all other foods, in breaking up disease and building up the patients after disease, preventing a relapse, **as the same results are obtained as in surgery.** Its value in surgical cases we illustrate by the records of the different cities and of Murdock's Free Surgical Hospital for Women, which is the largest in the United States. It contains 114 beds, every bed free, including operation, the operations ranging from 1000 to 1200 yearly, representing 90 of the worst classes known in surgery. Among these cases we have had **Cancer of uterus** (*Kolpo-hysterectomy*), 13; **Salpingitis** (*Tait's operation*), 31; **Fibroid of uterus** (*abdominal hysterectomy*), 19; **Ventral operation, hernia,** (*abdominal section*), 12; **Cancer of bowel** (*incision*), 2; **Parovarian cyst, 6; Papillomatous cyst** (*extirpation*), 4; **Tubercular peritonitis** (*incision*), 1, **Ovarian cystoma 27; Nymphomania** (*Battey*), 1; **Exploratory abdominal incisions, 12; Fibroid with abdominal abscess** (*Hegar*), 2; **Hysterorraphy, 2; Dermoid cyst, 3; Cirrhotic ovaries,** (*Battey*), 4; **Fibroid uterus** (*Hegar*), 6; **Hystero-epilepsy** (*Battey*), 1; **Haemato-Salpinx** (*Tait*), 5; **Rupture of intestine into vagina, 1; Dislocated kidney, 2; Fibroid tumor abdominal wall, 1; Resection of intestine** (*Senn*), 1; **Ruptured perineum, 294.** Patients are in the Hospital 8 days before and 26 days after operation, on an average.

In Boston, last year, 42 deaths were from Cancer in the Breast. In Murdock's Hospital, 35 such cases were operated on without a death, the patients remaining in the Hospital, on an average, 18 days.

Mortality in Boston,	25.60	per	1000.
" of Women in Boston,	29,00	"	"
" in **Murdock's Free Surgical Hospital,**	**5.00**	"	"
" New York,	26.32	"	"
" Philadelphia,	20.00	"	"
" Chicago,	20.90	"	"
" St. Louis,	20.49	"	"

showing our mortality is only one-sixth as great as of those in health. As good results were obtained in our General Hospital, which we kept open 27 months, **thus showing the value of nutrition as found in Murdock's Liquid Food, and so recognized by the British and American Medical Associations,** before which essays were read and discussed, and it is the only Raw food preparation on which essays were ever read.

Physicians are invited to visit our Hospitals and Works, also to send in patients and to be present at the operations. For any physician who has not used our Liquid Food (and Suppositories for adults and infants), we will deliver free samples to any express company in Boston.

When babies do not thrive, never change their food, but add five or more drops at each feeding of Murdock's Liquid Food, and their lost or needed vitality will be restored in less than thirty days. It is invaluable when weaning babies or when teething. If mothers will take one teaspoonful to a tablespoonful before each meal and on retiring, they will receive as much benefit as the baby.

Murdock Liquid Food Co., Boston.

CELERINA

NERVE TONIC, STIMULANT AND ANTISPASMODIC.

FORMULA.—Every Fluid Drachm represents FIVE grains EACH—Celery, Coca, Kola, Viburnum and Aromatics.

INDICATIONS.—Loss of Nerve-Power (so usual with Lawyers, Preachers, Writers and Business Men), Impotency, Spermatorrhea, Nervous Headache, Neuralgia, Paralysis, Hysteria, Opium Habit, Inebriety, Dyspepsia, and ALL LANGUID conditions of the System.

Indispensable to restore a patient after alcoholic excess.

DOSE.—One or two Teaspoonfuls three or more times a day, as directed by the Physician.

LIQUID IRON-RIO

Palatable and easily assimilated. Does not produce Nausea, nor irritate the Stomach. Does not Cause Headache, nor Constipate. Does not Stain the Teeth. It is so Acceptable to the Stomach that its Use is Admissible when all other forms of Iron would be rejected. Being so Readily Assimilable, it only requires a small Dose.

Each Fluid Drachm contains ONE GRAIN of Iron in a Pleasant and Digestible Form.

DOSE.—One or more Teaspoonfuls as indicated, during or after meals.

S. H. KENNEDY'S

CONCENTRATED EXTRACT OF

PINUS CANADENSIS

DARK. **A NON-ALCOHOLIC LIQUID.** WHITE.

A MOST VALUABLE NON-IRRITATING MUCOUS ASTRINGENT.

INDICATIONS.—Albuminuria, Diarrhea, Dysentery, Night-Sweats, Hemorrhages, Profuse Expectoration, Catarrh, Sore Throat, Leucorrhea, and other Vaginal Diseases, Piles, Sores, Ulcers, Burns, Scalds, Gonorrhea, Gleet, Etc.

When Used as an Injection, to Avoid Staining of Linen, the WHITE Pinus should be used.

RECOMMENDED BY PROMINENT EUROPEAN AND AMERICAN PHYSICIANS.

SPORTING AND ATHLETIC GOODS OF EVERY DESCRIPTION.

No Chemicals.

W. BAKER & Co.'S Breakfast Cocoa

Is Absolutely Pure, and it is Soluble.

To increase the solubility of the powdered cocoa, various expedients are employed, most of them being based upon the action of some alkali, potash, soda or even ammonia. Cocoa which has been prepared by one of these chemical processes, can usually be recognized at once by the distinct alkaline reaction of the infusion in water.

W. Baker & Co.'s Breakfast Cocoa is manufactured from the first stage to the last by perfect mechanical processes, **no chemical being used in its preparation.** By one of the most ingenious of these mechanical processes the greatest degree of fineness is secured without the sacrifice of the attractive and beautiful red color which is characteristic of an absolutely pure and natural cocoa.

BOUDAULT'S PEPSINE

The only Pepsine used in the Hospitals of Paris for the last Thirty Years.

Unlike the various substitutes which, in most cases, are but unscientific or incompatible compounds, forced upon the Medical Profession as aids to digestion by extensive advertising, but which, when submitted to the proper tests, are found to be useless as digestive agents, Pepsine is constantly gaining in the esteem of the careful practitioner.

Since the introduction of Pepsine by Boudault and Corvisart in 1854, the original BOUDAULT'S PEPSINE HAS BEEN AT ALL TIMES CONSIDERED THE BEST, as is attested by the awards it has received at the Expositions of 1867, 1868, 187 1873, in 1876 at the Centennial Exposition of Philadelphia, and in 1878 at the Paris Exposition.

The most reliable tests, carefully applied, will satisfy everyone that BOUDAULT'S PEPSINE HAS A MUCH HIGHER DIGESTIVE POWER than the best Pepsines now before the Profession, and is therefore especially worthy of their attention.

BOUDAULT'S PEPSINE is prepared in the form of Pepsine Acid and Pepsine Neutral. It is sold in bottles of one ounce, with a measure containing exactly five grains; also in bottles of four, eight, and sixteen ounces for dispensing.

BOUDAULT'S WINE OF PEPSINE

FORMULA OF DR. CORVISART.

The taste of Pepsine being perfectly disguised in this Wine, it may be recommended to persons who have difficulty in taking Pepsine in the form of Powder. This Wine is tested so that a tablespoonful of it is equal in digestive power to ten grains of Boudault's Pepsine in powder. Sold only in bottles of eight ounces.

TANRET'S PELLETIERINE

For the Treatment of Tape-Worm (Tænia Solium).

This New Tænifuge, the Active Alkaloid of Pomegranate Bark, has of late come into extensive use in France for the treatment of Tape-Worm (Tænia Solium). The results of numerous experiments with it at the Marine Hospitals of Toulon, St. Mandrier, etc., and in the Hospitals of Paris, St. Antoine, La Charité, Necker Beaujon, etc., have all been most satisfactory. Doctor Dujardin Beaumetz, Member of the Academy of Medicine, and Professor Laboulbene, in their report to the Society of Therapeutics, have given it their unqualified approval, after the most searching experiments. This preparation is pleasant to administer, and, if certain preliminaries are observed, success will be insured.

Sold only in bottles containing one dose.

DUCRO'S ALIMENTARY ELIXIR

A Combination uniting the properties of Alcoholic Stimulants and Raw Meat.

This preparation, which has been used with great success in the hospitals of Paris since 1868, is adapted to the treatment o all diseases requiring administration, in a small volume, of a tonic able to stimulate and support the vital forces, as *Pulmonar Phthisis, Depression and Nervous Debility, Adynamia, Malarious Cachexia, etc.*

Prepared by EMILE DURIEZ & CO., Successors to DUCRO & CIE, Paris.

KIRKWOOD'S INHALER

This is the only complete, reliable, and effective inhaler in use, arranged for the direct application of Muriate of Ammonia and other remedial agents in the state of vapor to the diseased parts of the air-passages in the treatment of catarrh and diseases of the throat and lungs. No heat or warm liquids required in its use.

It is entirely different from the various frail, cheap instruments that have been introduced.

KIRKWOOD'S INHALER is accompanied by testimonials of the highest professional character, together with carefully prepared formulas for use.

RETAIL PRICE, COMPLETE, $2.50.

☞ A liberal discount allowed to the trade and profession. For descriptive pamphlet or other information address

GEORGE W. MILTENBERGER, M.D.,
Professor of Obstetrics.
CHRISTOPHER JOHNSON, M.D.,
Emeritus Professor of Surgery.
SAMUEL C. CHEW, M.D.,
Professor of Principles and Practice of Medicine and Hygiene.
FRANK DONALDSON, M.D.,
Emeritus Clinical Professor of Diseases of the Throat and Chest.
WILLIAM T. HOWARD, M.D.,
Professor of Diseases of Women and Children and Clinical Medicine.
JULIAN J. CHISOLM, M.D.,
Professor of Eye and Ear Diseases.
FRANCIS T. MILES M.D.,
Professor of Physiology and Clinical Professor of Diseases of Nervous System.

L. McLANE TIFFANY, M.D.,
Professor of Surgery.
J. EDWIN MICHAEL, M.D.,
Professor of Anatomy and Clinical Surgery.
I. EDMONSON ATKINSON, M.D.,
Professor of Materia Medica and Therapeutics, Clinical Medicine and Dermatology.
R. DORSEY COALE, PH.D.,
Professor of Chemistry and Toxicology.
JOHN NOLAND MACKENZIE, M.D.,
Clinical Professor of Diseases of the Throat and Nose.
HERBERT HARLAN, M.D.,
Demonstrator of Anatomy.

For catalogue and further information, address: **Dr. J. EDWIN MICHAEL, Dean, 937 Madison Avenue.**

DENTAL DEPARTMENT.

Eighth Annual Announcement. Next regular session begins October 1st, 1889. New and excellent Infirmary and Laboratory, with abundance of clinical material.

FACULTY:

FRED. J. S. GORGAS, M.D., D.D.S.,
Professor of Principles of Dental Science, Dental Surgery, and Dental Mechanism.
JAMES H. HARRIS, M.D., D.D.S.,
Professor of Operative and Clinical Dentistry.
I. EDMONSON ATKINSON, M.D.,
Professor of Materia Medica and Therapeutics.
FRANCIS T. MILES, M.D.,
Professor of Physiology.
L. McLANE TIFFANY, M.D.,
Clinical Professor of Oral Surgery.

J. EDWIN MICHAEL, M.D.,
Professor of Anatomy.
R. DORSEY COALE, PH.D.,
Professor of Chemistry.
JOHN C. UHLER, M.D., D.D.S.,
Demonstrator of Mechanical Dentistry.
CHAS. L. STEEL, M.D., D.D.S.,
Demonstrator of Operative Dentistry.
HERBERT HARLAN, M.D.,
Demonstrator of Anatomy.
AND EIGHT ASSISTANT DEMONSTRATORS.

For catalogue and other information, apply to **Dr. F. J. S. GORGAS, Dean, 845 Eutaw Street, Baltimore.**

Medico-Chirurgical College of Philadelphia.

JAS. E. GARRETSON, A.M., M.D., Professor of Oral and Clinical Surgery.

WM. H. PANCOAST, A.M., M.D., Professor of General, Descriptive, and Surgical Anatomy and Clinical Surgery.

GEO. E. STUBBS, A.M., M.D., Professor of Clinical Surgery.

WM. F. WAUGH, A.M., M.D., Professor of Principles and Practice of Medicine and of Clinical Medicine.

ABRAHAM S. GERHARD, A.M., M.D., Professor of Forensic and Clinical Medicine.

WM. S. STEWART, A.M., M.D., Professor of Obstetrics and Clinical Gynecology.

H. EARNEST GOODMAN, M.D., Professor of Principles and Practice of Surgery and Clinical Surgery.

P. D. KEYSER, A.M., M.D., Dean, Professor of Ophthalmology.

SAMUEL B. HOWELL, A.M., M.D., Professor of Chemistry.

JOHN V. SHOEMAKER, A.M., M.D., Professor of Materia Medica, Pharmacology, Therapeutics and Clinical Medicine.

E. E. MONTGOMERY, B.S., M.D., Professor of Gynecology.

JAS. M. ANDERS, Ph.D., M.D., Professor of Hygiene and Clinical Diseases of Children; Associate Professor of Physiology

JOHN V. SHOEMAKER, A.M., M.D., Clinical Professor Skin Diseases.

FRANK WOODBURY, A.M., M.D., Honorary Professor of Clinical Medicine.

WM. B. ATKINSON, A.M., M.D. Honorary Professor of Sanitary Science and Paediatrics.

The Regular Session begins September 30th, 1889, and continues until the middle of April. It is preceded by a Preliminary Session of three weeks, and followed by a Spring Session lasting until the middle of June.

Seats are issued in the order of matriculation, and are forfeitable if fees are not paid before November 1st.

Preliminary examination or equivalent degree, and a three years' graded course obligatory. A fourth year voluntary.

Instruction is given by lectures, clinical teaching and practical demonstrations. In the subjects of Anatomy, Pharmacy, Chemistry, Histology and Pathology the usual methods of instruction are largely supplemented by laboratory work.

Examinations are held at the close of each Regular Session upon the studies of the term. Although the degree of Doctor of Medicine is conferred at the end of the third year, a fourth year is earnestly recommended, at the end of which the degree of Doctor of Medicine *cum laude* is given.

FEES.

Matriculation, $5: first and second years, each, $100; third year (no graduation fee), $100; fourth year, free to those who have attended three sessions in this school, to all others, $100.

Extra charges only for material used in the laboratories and dissecting-room.

For further information or announcement, address,

E. E. MONTGOMERY, M.D., Secretary,
Medico-Chirurgical College,
Cherry, below 18th Street, Philadelphia, Penna.

Medical College of Ohio.

Medical Department of the University of Cincinnati.

The Seventy-first Annual Session will begin September 4, 1889, and continue until March 1, 1890.

FEES.—Matriculation Ticket, $5.00; General Lecture Ticket, $75.00; Hospital Ticket, $5.00; Graduation Fee, $25.00.

For circulars, and further information, address
JAMES G. HYNDMAN, M.D., Secretary,
22 West Ninth Street, Cincinnati, Ohio.

WESTERN PENNSYLVANIA MEDICAL COLLEGE

CITY OF PITTSBURGH.

SESSIONS OF 1889—90.

The REGULAR SESSION begins on the last Tuesday of September, and continues six months. During this session, in addition to four Didactic Lectures, two or three hours are daily allotted to Clinical Instruction. Attendance upon two regular courses of lectures is requisite for graduation. A three years' graded course is also provided. The SPRING SESSION embraces recitations, clinical lectures and exercises, and didactic lectures on special subjects; this session begins the second Tuesday in April, and continues ten weeks.

The laboratories are open during the collegiate year for instruction in chemistry, microscopy, practical demonstrations in medical and surgical pathology, and lessons in normal histology. Special importance attaches to "the superior clinical advantages possessed by this College." For particulars, see annual announcement and catalogue, for which, address the Secretary of Faculty, Prof. J. W. J. McKENNAN.

Business correspondence should be addressed to
PROF. W. J. ASDALE, 2107 Penn Avenue, Pittsburgh.

Woman's Medical College
OF BALTIMORE.

S. E. Cor. Druid Hill Ave. and Hoffman St., Baltimore, Md.

THE EIGHTH ANNUAL SESSION WILL BEGIN ON WEDNESDAY, OCTOBER 2d, 1889.

For further information or catalogue, address
RANDOLPH WINSLOW, M.D., Acting Dean,
No. 1, Mount Royal Terrace, Baltimore, Md.

Medical Department, State University of Iowa, at Iowa City, Iowa.

The next Session will begin on September 11, 1889, and continue until March 12, 1890. Attendance upon three courses of lectures, of six months each, is requisite to graduation. The facilities for dissection and clinical study are unsurpassed.

TERM EXPENSES—Lecture Ticket, $20.00; Demonstrator's Ticket, $10.00; Matriculation Ticket, $5.00 (paid but once); Hospital Ticket $1.00; Examination Fee (for final examination) $25.00. No charge for dissecting material. For further information, address DR. A. C. PETERS, Ast. Sec'y, Iowa City, Iowa.

A STENOGRAPHER accustomed to medical work, would like a morning engagement. Surgeon preferred. References unexceptionable. Address, C,

4t. MEDICAL AND SURGICAL REPORTER.

TABLETS OF SULPHIDE OF ARSENIC

(as suggested by Dr. Louis Lewis) for the treatment of acne, eczema, furuncle, anthrax, psoriasis, etc., may be obtained from WILMOT HANSELL, Druggist, 1626 Market St., Philadelphia. Price, $1.00 per box of 200.

See leading article in "MEDICAL WORLD," February, 1889.

DETROIT COLLEGE OF MEDICINE.

SESSION 889-90.

Clinical and Practical teaching are made an important feature of this College. Clinical instruction is given daily at HARPER, ST. MARY'S and ST. LUKE'S HOSPITAL, at the COLLEGE, at COLLEGE EYE and EAR INFIRMARY, ST. MARY'S FREE EYE and EAR INFIRMARY, and at the three FREE DISPENSARIES. The facilities offered by this college are unsurpassed for the practical study of MEDICINE, SURGERY, OBSTETRICS, GYNÆCOLOGY, DISEASES OF CHILDREN, GENITO-URINARY, and ORTHOPÆDIC SURGERY, OPHTHALMOLOGY and OTOLOGY, DERMATOLOGY and LARYNGOLOGY.

REGULAR SESSION opens on Wednesday, Sept. 25, and continues six months. During the session, the Professors will take special pains to examine the Students upon the subjects of the previous lectures.

SPRING SESSION begins April 2d, 1890; and closes June 11th.

FEES.—Matriculation fee, $5; Fees for Regular Session, $50; Spring Session, $10, to those who attend the regular term—to all others, $25; Hospital Fee, $10; Graduation Fee, $30; Perpetual Ticket, $100.

For further particulars, and for College Circular, apply to

H. O. WALKER, M.D., Secretary,
33 Lafayette Ave., Detroit, Mich.

UNIVERSITY OF PENNSYLVANIA.—Medical Department.

The 124TH ANNUAL WINTER SESSION will begin Tuesday, October 1st, 1889, at 12 M., and continue until May 1st, 1890.
The PRELIMINARY SESSION begins September 18th, 1889.
The curriculum is graded and three annual winter sessions are required. Practical instruction, including laboratory work in Chemistry, Histology, Osteology and Pathology, with Bedside Instruction in Medicine, Surgery and Gynecology are a part of the regular course and without additional expense.

FACULTY.

JOSEPH LEIDY, M.D., LL.D., Professor of Anatomy.
D. HAYES AGNEW, M.D., LL.D., Honorary Professor of Clinical Surgery
WILLIAM PEPPER, M.D., LL.D., Professor of Theory and Practice of Medicine, and of Clinical Medicine.
WILLIAM GOODELL, M.D., Professor of Gynecology.
JAMES TYSON, M.D., Professor of Clinical Medicine.
HORATIO C. WOOD, M.D., LL.D., Professor of Materia Medica, Pharmacy and General Therapeutics.
THEODORE G. WORMLEY, M.D., LL.D., Professor of Chemistry and Toxicology.
JOHN ASHHURST, JR., M.D., Professor of Surgery and of Clinical Surgery.
EDWARD T. REICHERT, M.D., Professor of Physiology.

ELIXIR COCA AND CALISAYA

(S. & O.)

A valuable nerve stimulant and tonic, entirely different from any other preparation of Coca or Calisaya. Made by a process which brings out in the highest degree the active principles of fresh

COCA LEAVES AND CINCHONA BARK.

Free from bitter taste or depressing effects after using. It is recommended to physicians as useful in Atonic Indigestion, Insomnia, Nervous Exhaustion, Mental Depression, etc.

Made only by

STRYKER & OGDEN,

Walnut and 13th Streets, Philadelphia.

PHYSICIANS' OFFICE AND OPERATING

COATS.

MADE OF BLEACHED DRILLING;
WILL NOT SHRINK IN WASHING.

$1.25 each; $7.00 per ½ Dozen.

Single Coats by Post, 15 cents additional.

HIRSH, FRANK & CO.,

31 North Third St., Philadelphia.

☞In ordering, send chest measure and length of sleeve from middle of back.

The only prominent Emulsion of Cod-Liver Oil introduced directly to the medical profession. It is advertised exclusively in medical journals.

HYDROLEINE.

(HYDRATED OIL.)

Produces rapid increase in Flesh and Strength.

FORMULA.—Each Dose contains:			
Pure Cod Liver Oil.....80 m. (drops)		Soda.....1-3 Grains.	
Distilled Water.....35 "		Salicylic Acid.....1-4 "	
Soluble Pancreatin..... 5 Grains.		Hycholic Acid.....1-90 "	

Recommended and Prescribed by EMINENT PHYSICIANS Everywhere. It is pleasant to the Taste and acceptable to the most delicate Stomach.

IT IS ECONOMICAL IN USE AND CERTAIN IN RESULTS.

HYDROLEINE (Hydrated Oil) is not a simple alkaline emulsion of oleum morrhuæ, but a hydro-pancreated preparation, containing acids and a small percentage of soda. Pancreatin is the digestive principle of fatty foods, and in the soluble form here used, readily converts the oleaginous material into assimilable matter, a change so necessary to the reparative process in all wasting diseases.

The following are some of the diseases in which **HYDROLEINE** is indicated:)

Phthisis, Tuberculosis, Catarrh, Cough, Scrofula, Chlorosis,

General Debility, etc.

TO BRAIN WORKERS of all classes, **HYDROLEINE** is invaluable,—supplying as it does, the true brain-food, and being more easily assimilated by the digestive organs than any other emulsion.

The principles upon which this discovery is based have been described in a treatise on "The Digestion and Assimilation of Fats in the Human Body," and "Consumption and Wasting Diseases," by two distinguished London physicians, which will be sent free on application.

SOLD BY DRUGGISTS GENERALLY.

C. N. CRITTENTON,

SOLE AGENT FOR THE UNITED STATES. 115 FULTON STREET, N. Y.

A Sample of Hydroleine will be sent free upon application, to any physician (enclosing business card) in the U. S.

We make Shoes which insure HEALTH, EASE AND COMFORT. Ready-made or to Measure.

Illustrated Catalogue sent on application. (Mention this Journal.)

WE ARE CONFIDENT THAT WE HAVE REACHED THE **Highest Degree of Perfection** *IN SOLVING THE* **INFANT FOOD PROBLEM.**

Lacto-Preparata.

A Prepared Human Milk perfectly Sterilized and especially designed for Children from birth to six or eight months of age.

Made wholly from cow's milk with the exception that the fat of the milk is partially replaced by cocoa butter. Cocoa butter is identical with milk fat in food value and digestibility, being deficient only in the principle which causes rancidity. The milk in *Lacto-Preparata* is treated with Extract of Pancreas at a temperature of 105 degrees, a sufficient length of time to render twenty-five per cent. of the casein soluble, and partially prepare the fat for assimilation. In this process the remaining portion of the casein not peptonized, is acted upon by the pancreatic ferment in such a manner as to destroy its tough tenacious character, so that it will coagulate in light and flocculent curds, like the casein in human milk.

Composition:

ALBUMINOIDS,	19 Parts.
MILK SUGAR,	64 "
FAT,	10 "
MINERAL MATTER,	3 "
CHLORIDE of SODIUM added,	½ "
PHOSPHATES of LIME added,	½ "
MOISTURE,	3 "

SEND FOR SAMPLE and compare it with every other food used in artificial feeding of Infants.

Lacto-Preparata is not designed to replace our **Soluble Food**, but is better adapted for Infants up to eight months of age.

Carnrick's Soluble Food

Is the Nearest Approach to Human Milk that has thus far been produced, with the exception of Lacto-Preparata.

During the past season a large number of Physicians and eminent Chemists visited our Laboratory at Goshen, N. Y., and witnessed every detail connected with the production of Carnrick's Soluble Food. This invitation to witness our process is continuously open to Physicians and Chemists. All expenses from New York to Goshen and return will be paid by us. The care used in gathering the milk, its sterilization, and the cleanliness exercised in every step, cannot be excelled. Soluble Food has been improved by increasing the quantity of milk sugar and partially replacing the milk fat with cocoa butter.

Phospho-Caffein Comp.

(GRANULAR EFFERVESCING.)

A SEDATIVE, NERVE AND BRAIN FOOD.

This preparation has been thoroughly tested, and found to produce the happiest effects in Headaches, Neuralgia, Sleeplessness, and General Nervous Irritability. We are confident that the above combination will be found superior to any of the various preparations that are used in nervous affections. It is not only a nerve sedative, but a Brain and Nerve Food. The depressing effects of the sedative ingredients are fully overcome by its reconstructive constituents.

As a harmless and positive remedy in Headaches and Insomnia, we are certain it has no equal It is far more palatable than any of the preparations used for similar purposes.

PUT UP IN FOUR, EIGHT, AND THIRTY-TWO OUNCE BOTTLES.

REED & CARNRICK, New York.

Champagne ANALYZED

Of Interest to all Medical Practitioners.

WHAT IS SAID BY

THOMAS KING CHAMBERS, M.D., F.R.C.P.
R. OGDEN DOREMUS, M.D.
F. W. PAVY, M.D., F.R.S.

"Champagne, with a minimum of alcohol, is by far the wholesomest, and possesses remarkable exhilarating power."—THOMAS KING CHAMBERS, M.D., F.R.C.P.

"Having occasion to investigate the question of wholesome beverages, I have made a chemical analysis of the most prominent brands of Champagne. I find G. H. Mumm & Co.'s Extra Dry to contain, in a marked degree, less alcohol than the others. I therefore most cordially commend it not only for its purity but as the most wholesome of the Champagnes."—R. OGDEN DOREMUS, M.D., *Professor of Chemistry, Bellevue Hospital Medical College, New York.*

"Champagne, while only possessing the alcoholic strength of natural wines, is useful for exciting the flagging powers in case of exhaustion."—F. W. PAVY, M.D., F.R.S., *Lecturer on Physiology at Guy's Hospital, London.*

The remarkable vintage of 1884 of **G. H. MUMM & CO.'S EXTRA DRY CHAMPAGNE,** the finest for a number of years, is now imported into this market, and pronounced by connoisseurs unsurpassed for excellence and bouquet.

THIRD EDITION.

ACCIDENTS AND EMERGENCIES

By CHARLES W. DULLES, M.D.

"A work that ought to be in every home, and every home that has a copy kept where it can be consulted at short notice is likely to find it worth many times its small cost."—*Philadelphia Evening Telegraph,* May 5, 1888.

"The methods of treatment recommended are trustworthy and reliable. The manual is one of the best of this class of books and should be in the library of every householder, ready for reference at a moment's notice."—*Science,* May 18, 1888.

Sent on receipt of 75 Cents.

ADDRESS:

Publisher **Medical and Surgical Reporter,**

P.O. Box 843. PHILADELPHIA, PA.

The utility of artificial legs and arms with rubber feet and hands is evidenced by the operations of over nine thousand men, women, and children distributed throughout the entire civilized world. Strange as it may seem, this army mingles with the vast populace and their misfortunes are lost to sight. Men engaged in all manner of vocations, manual, arduous, menial, on the farm, at the forge, in the mines, at the desk. Women attend to their household duties, whether in the kitchen, laundry, drawing-room, or parlor. Children wearing one or a pair of artificial limbs are no longer objects of pity and dependence; they indulge with other children in all manner of sports, they skate, ride the bicycle, romp and tumble about just as healthy and merry children should do.

One little fellow from Connecticut writes: "I can climb trees, play base-ball, and other out-door games as well as other 14-year-old boys."

A large illustrated book, containing 400 pages and over 200 illustrations, will be sent free to those needing artificial legs and arms, or to physicians and others interested.

This book gives instructions how to order and be fitted while the subject remains at home.

A. A. MARKS, 701 Broadway, New York City.

ESTABLISHED OVER 36 YEARS.

McARTHUR'S SYRUP.

(SYR: HYPOPHOS: COMP: C. P. McARTHUR.)

Its use is indicated in Consumption and Tuberculosis, Diseases of the Chest, Chronic Cough, Throat Affections, General Debility, Brain Exhaustion, Impotence and Loss of Memory.

The point of primary importance in the use of the Hypophosphites is their *chemical* purity, but unfortunately they are too often adulterated.

So little seems to be generally known, even among the medical profession, with regard to the chemistry of the Hypophosphites, and the absolute necessity of CHEMICAL purity, that we call attention to this point.

One of the first effects produced by the use of our CHEMICALLY PURE Hypophosphites is a general increase of nervous energy, with a feeling of ease and comfort.

The second effect is an increase of appetite; digestion is improved, and the bowels become regular in their action, the quantity and color of the blood is increased, respiration is controlled, a better expansion of the chest is observed, cough improves, easy expectoration is produced, night perspiration diminishes, the face becomes fuller, the lips red, the nails and hair grow, and in children the teeth, showing the importance of the Hypophosphites on the organ of nutrition.

☞ Physicians when prescribing will please write thus:

℞ SYR: HYPOPHOS: COMP: McARTHUR. ONE BOTTLE.

As it is made *only for physicians* there are no printed wrappers or advertisements about the bottle.

Our pamphlet on the **CURABILITY AND TREATMENT OF CONSUMPTION,** sent free to physicians upon application.

We will send one bottle of McArthur's Syrup to any physician, without charge, who will pay the express charges on the same.

Mention this Journal. McARTHUR HYPOPHOSPHITE CO., BOSTON, Mass.

THE NEW HYPNOTIC
SULFONAL-BAYER.

SULFONAL was discovered by Prof. Eugen A. Baumann, of Freiburg University, and was first prepared by the Farbenfabriken vorm. Friedr. Bayer & Co., Elberfeld.

SULFONAL (Diæthylsulfondimethylmethan) is in the form of colorless prisms, odorless, and tasteless, melting at 125.5° C. (258° F.) and has the composition $(C H_3)_2=C=(C_2 H_5 SO_2)_2$. It is slightly soluble in cold water, but easily soluble in hot water or alcohol.

SULFONAL was first examined as to its physiological and pathological effects by Prof. A. Kast, of Freiburg University, and its hypnotic action was discovered and studied by him.

Since then SULFONAL has been the subject of numerous trials and experiments by many eminent and experienced physicians. Their testimony is unanimously favorable, and the conclusions reached by them are as follows:

SULFONAL is a prompt and reliable hypnotic, which in proper doses, produces quiet, natural sleep, lasting a number of hours.

SULFONAL has no unfavorable effects on the heart and the circulation, nor on the temperature, the pulse, or the respiration.

SULFONAL produces no disagreeable secondary symptoms; the patients with very few exceptions awake from their sleep feeling strong and greatly refreshed.

SULFONAL does not interfere with the process of digestion.

SULFONAL is a hypnotic, and not a narcotic; it acts by giving rest to the cells of the cerebral cortex, thereby causing sleep.

SULFONAL does not create an unconquerable desire for its repeated use; there is no danger of a SULFONAL-habit. Neither is it necessary to increase the dose after long-continued use.

SULFONAL is best administered at supper-time, dissolved in hot liquids, *e. g.*, a bowl of soup or broth, a cup of milk, tea, coffee, cocoa, etc.

These points will be found to be fully exhibited in the series of contributions contained in our pamphlet, which will be mailed on application.

SULFONAL-BAYER is supplied by us in half-ounce and one-ounce vials.

We prepare 5-grain and 15-grain Tablets of Sulfonal-Bayer. The tablet form is admirably adapted to the purpose of administering this drug, as when they are placed in the liquids, they disintegrate and are thus received into the system.

We also put up Sulfonal-Bayer in the form of our Soluble Pills, containing five grains each.

THE NEW ANTIPYRETIC
PHENACETINE-BAYER.

Phenacetine-Bayer (Para-Acetphenetidine) is a white, glossy, crystalline powder, perfectly tasteless, melting at 135° C.=307° F and has the composition $C_6 H_4 <^{O.C_2H_5}_{NH(CO-CH_3)}$.

It is slightly soluble in water, a little more soluble in glycerine, but most freely in alcohol.

Phenacetine-Bayer was first prepared by the Farbenfabriken, formerly Friedr. Bayer & Co., Elberfeld, and is of absolute purity and uniform quality.

Summarizing the superiority of Phenacetine-Bayer over other antipyretics and antineuralgics, the following conclusions are formed:

1. ***Phenacetine-Bayer is an efficacious antipyretic.***
2. ***It does not develop any disagreeable or noxious after-effects.***
3. ***The dose required is half that of Antipyrine.***
4. ***It is perfectly tasteless.***
5. ***On account of its innocuousness and tastelessness, it is a valuable antipyretic both in adults and in children.***
6. ***Phenacetine-Bayer is an important antineuralgic; its effect is more energetic than that of Antipyrine and does not cause lassitude or any other disagreeable symptoms.***

Our pamphlet on Phenacetine-Bayer, containing the valuable testimony of eminent physicians will be mailed on application.

We offer Phenacetine-Bayer in one-ounce vials, or in the form of our Soluble Pills of the strength of two and four grains to each pill.

PILLS OF DR. MOUSSETTE.

The **Moussette Pills** of aconitine and quinium, calm or cure *Gastralgia, Hemicrania, Headache, Sciatica*, and the most obstinate Neuralgias.

"The sedative action exerted by the **Moussette Pills** "upon the apparatus of the sanguineous circulation by the "intermediation of the vaso-motor nerves, indicates their "use in *neuralgias of the trigemini nerves*, (fifth pair), *con- "gestive neuralgias*, and *painful and inflammatory Rheumatismal "affections*."

"Aconitine produces marvelous effects in the treatment "of *facial neuralgias* when they are not symptomatic of "intracranial tumor."—*Society of Biology of Paris, Meeting "of the 28th February, 1880.*

Dose—Take 3 to 6 pills during the twenty-four hours.

ACCEPT ONLY THE GENUINE MOUSSETTE PILLS OF

CLIN & CO.,—Paris.

GRAND NATIONAL PRIZE OF 16,600 FRANCS,

QUINA-LAROCHE

This meritorious **Elixir, QUINA-LAROCHE,** is prepared from the three Cinchonas; it is an agreeable and doubtless highly efficacious remedy.

—*The Lancet.*

VINOUS ELIXIR,

A STIMULATING RESTORATIVE

—AND—

ANTI-FEBRILE TONIC.

QUINA-LAROCHE under the form of a vinous **Elixir** contains the totality of the numerous principles of the three Cinchona barks. It is a preparation which renders great services to Therapeutics.—Extract of the *Gazette des Hôpitaux*, Paris.

FAR SUPERIOR TO ALL ORDINARY CINCHONA WINES.

LAROCHE'S QUINA, tried by the Academy of Medicine of Paris, is a specially prepared COMPOUND EXTRACT of Quinquina, a careful analysis, confirmed by experience, has shown that most of the wines and syrups hitherto used have not contained all the properties of this precious bark, of these some, although beneficial, are altogether lost, while many preparations contain but half the properties of the bark in varying proportions.

MR. LAROCHE, by his peculiar method, has succeeded in extracting all the active principles of the quinquina, combining these with *Catalan Wine* forming an Elixir free from the disagreeable bitterness of other similar preparations. Practitioners have found triple advantages in the use of this Elixir, it is a *strong tonic*, is easily administered, and perfectly harmless, being free from the unpleasant effects of Quinine.

THE FERRUGINOUS QUINA-LAROCHE is the invigorating tonic *par excellence*, having the advantage of being easily assimilated by the gastric juice; without, in any way, deranging the action of the digestive organs, proving itself to be a most efficacious remedy in cases of impoverishment of the blood, ANÆMIA, CHLOROSIS, INTESTINAL HÆMORRHAGE, CASTRALGIA, EXHAUSTION, ETC., ETC.

PARIS.—22 RUE DROUOT.—PARIS.

BROMIDIA

THE HYPNOTIC.

FORMULA.—

Every fluid drachm contains 15 grains EACH of Pure Chloral Hydrat. and purified Brom. Pot., and one-eighth grain EACH of gen. imp. ext. Cannabis Ind. and Hyoscyam.

DOSE.—

One-half to one fluid drachm in WATER or SYRUP every hour, until sleep is produced.

INDICATIONS.—

Sleeplessness, Nervousness, Neuralgia, Headache, Convulsions, Colic, Mania, Epilepsy, Irritability, etc. In the restlessness and delirium of fevers it is absolutely invaluable.

IT DOES NOT LOCK UP THE SECRETIONS.

PAPINE

THE ANODYNE.

Papine is the Anodyne or pain-relieving principle of Opium, the Narcotic and Convulsive Elements being eliminated. It has less tendency to cause Nausea, Vomiting, Constipation, Etc.

INDICATIONS.—

Same as Opium or Morphia.

DOSE.—

(ONE FLUID DRACHM)—represents the Anodyne principle of one-eighth grain of Morphia.

IODIA

The Alterative and Uterine Tonic.

FORMULA.—

Iodia is a combination of active principles obtained from the Green Roots of Stillingia, Helonias, Saxifraga, Menispermum, and Aromatics. Each fluid drachm also contains five grains Iod. Potas., and three grains Phos. Iron.

DOSE.—

One or two fluid drachms (more or less as indicated) three times a day before meals.

INDICATIONS.—

Syphilitic, Scrofulous and Cutaneous Diseases, Dysmenorrhea, Menorrhagia, Leucorrhea, Amenorrhea, Impaired Vitality, Habitual Abortions, and General Uterine Debility.

THE SUSTAINED SUPREMACY

OF

Fairchild's Pepsin,

In ACTIVITY, PERMANENCE and GENERAL EXCELLENCE

Has won for this product a wide use and recognition in all the principal markets of the world.

We guarantee it to be unchangeable, to maintain its activity and quality under all ordinary commercial conditions; it is therefore, by far the most available for the dispensing counter, as well as in the manufacture of every form of pepsin preparation.

Under exactly parallel conditions, with any proper percentage of acidity and with any proportion of such acidulated water to the albumen, Fairchild's pepsin is positively superior to any pepsin known.

It will, under absolutely comparative conditions, grain for grain, digest more albumen than any other pepsin made.

We will be pleased to send samples to any physician who may wish to ascertain for himself the relative activity of Fairchild's pepsin, or to submit it to any practical trial.

Prices and complete information upon application.

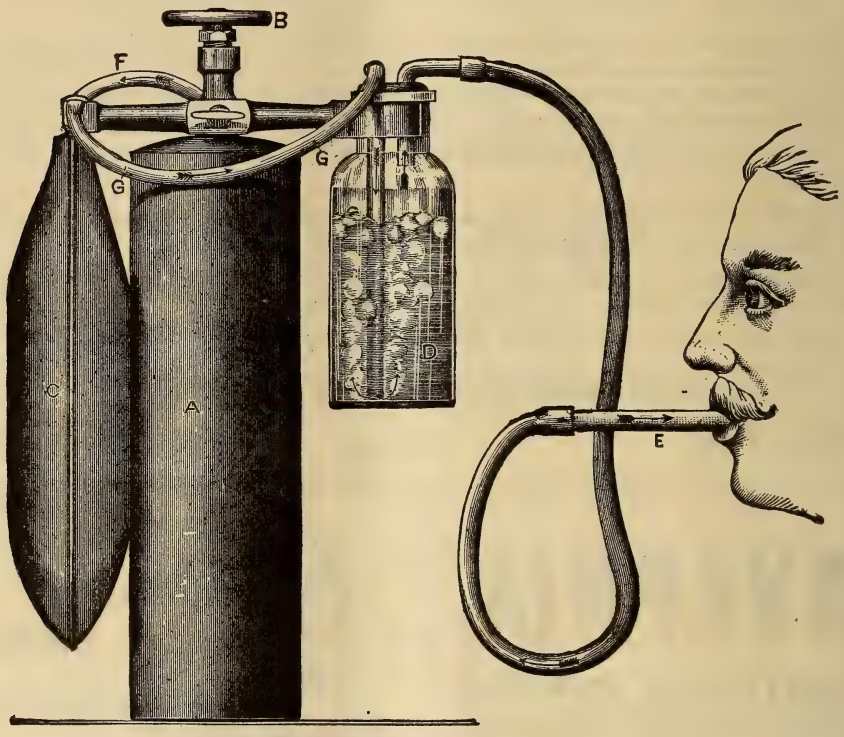
INHALATION APPARATUS

FOR

THE THERAPEUTIC ADMINISTRATION OF OXYGEN.



In the treatment of lung troubles by Oxygen its exhibition by inhalation is preferred. The apparatus herewith shown is a modification of the Nitrous Oxide apparatus which we have supplied for many years. It is made in the best manner throughout, and is the outcome of years of experience in the manufacture of gas apparatus. It will be found to meet all the requirements.

We supply the gas in two sizes of cylinders, containing respectively forty and one hundred gallons, either pure Oxygen, or a mixture of Oxygen and Nitrous Oxide in definite proportions of 20 per cent., and forty per cent. of Nitrous Oxide.

Whether pure or mixed the gas is sold at the uniform price of 5 cents a gallon. The cost of the cylinders will be refunded on their return empty with the valves in good condition. Full description of Inhalation and Enema apparatuses with directions for use accompany each apparatus, or will be supplied on application.

PRICES.

Inhalation Apparatus	$5.00
Cylinder, 40 gallons' capacity	6.00
40 gallons Gas, either pure Oxygen or mixed Oxygen and Nitrous Oxide	2.00
Complete Apparatus, Cylinder, and 40 gallons Gas	$13.00
Inhalation Apparatus	$5.00
Cylinder, 100 gallons' capacity	15.00
100 gallons Gas, either pure or mixed	5.00
Complete Apparatus, Cylinder, and 100 gallons Gas	$25.00

THE BEST ANTISEPTIC
FOR BOTH INTERNAL AND EXTERNAL USE.

ANTISEPTIC, PROPHYLACTIC, DEODORANT.

LISTERINE

NON-TOXIC, NON-IRRITANT, NON-ESCHAROTIC.

FORMULA—Listerine is the essential antiseptic constituent of Thyme, Eucalyptus, Baptisia, Gaultheria and Mentha Arvensis, in combination. Each fluid drachm also contains two grains of refined and purified Benzo-boracic Acid.

DOSE—Internally: One teaspoonful three or more times a day (as indicated) either full strength, or diluted, as necessary for varied conditions.

LISTERINE is a well-proven antiseptic agent—an antizymotic—especially adapted to internal use, and to make and maintain surgical cleanliness—asepsis—in the treatment of all parts of the human body, whether by spray, irrigation, atomization, or simple local application, and therefore characterized by its particular adaptability to the field of

PREVENTIVE MEDICINE—INDIVIDUAL PROPHYLAXIS.

Diseases of the Uric Acid Diathesis.

LAMBERT'S

LITHIATED HYDRANGEA

KIDNEY ALTERATIVE—ANTI-LITHIC.

FORMULA—Each fluid drachm of "Lithiated Hydrangea" represents thirty grains of FRESH HYDRANGEA and three grains of CHEMICALLY PURE Benzo-Salicylate of Lithia. Prepared by our improved process of osmosis, it is INVARIABLY of DEFINITE and UNIFORM therapeutic strength, and hence can be depended upon in clinical practice.

DOSE—One or two teaspoonfuls four times a day (preferably between meals).

Urinary Calculus, Gout, Rheumatism, Bright's Disease, Diabetes, Cystitis, Hæmaturia Albuminuria, and Vesical irritations generally.

We have much valuable literature upon { GENERAL ANTISEPTIC TREATMENT, LITHEMIA, DIABETES, CYSTITIS, ETC. } To forward to Physicians upon request.

21 Park Place N.Y.

Geo Hamlin Prest. Chas Roome Parmele Treas.

GENTLEMEN:

The Case of your wines sent me for analysis by Dr. A. L. Hummel, of the "Annals of Hygiene," containing specimens of your La Rosa Zinfandel, Mataro, Riesling, Royal Tokay, and Royal Grape Brandy, has been duly received.

I have examined them for the common contaminants of wine; to wit: Sulphurous acid and sulphites, salicylic acid, fuchsin, lead salts, etc., none of which I found present therein.

I have also determined their alcoholic strength, extractives, and ashes, and found them to correspond strictly in this respect with the standard of pure and natural wines, which cannot be said of many of the imported wines.

As a native of a wine-producing country, I consider myself somewhat of a judge of wines, and regard your products as comparing more than favorably with most of the wines from abroad which are sold at higher prices, so much so that I enclose within my order for fifty bottles of La Rosa Zinfandel, which I expect to use hereafter exclusively at my table.

Very Respectfully,

L. WOLFF, M.D.,
Demonstrator of Chemistry, Jefferson Medical College.

NEW AND RELIABLE RECIPES FOR PHYSICIANS PRESCRIBING.

In order to get the full therapeutic effects, physicians will please specify (WARNER & CO.) when ordering or prescribing.

☞The coating of the following pill will dissolve in 4½ minutes.☜

PIL: CHALYBEATE COMP.

(WARNER & CO.)

Nux Vomica is added as an ingredient to Pill Chalybeate to increase the tonic effect when desired.
Composition of each Pill.—℞ (Chalybeate Mass.), Carb. Protoxide of Iron, gr. 2½., Ext. Nuc. Vom. gr. 1-6.

DOSE—1 to 3 Pills.

Most advantageously employed in the treatment of Anæmia, Chlorosis, Phthisis, Scrofula, Loss of Appetite, etc.

PIL: ANTISEPTIC.

Each Pill contains: Sulphite Soda, 1 gr. Salicylic Acid, 1 gr. Ext. Nuc. Vomica, ¼ gr.

DOSE—1 to 3 Pills.

Pil. Antiseptic is prescribed with great advantage in cases of Dyspepsia attended with acid stomach and enfeebled digestion following excessive indulgence in eating or drinking. It is used with advantage in Rheumatism.

Prepared by WM. R. WARNER & CO.

PIL: ANTISEPTIC COMP.

(WARNER & CO.)

Each Pill contains: Sulphite Soda, 1 gr. Salicylic Acid. 1 gr. Ext. Nuc. Vomica, ⅛ gr. Powd. Capsicum, 1-10 gr. Conc'd Pepsin, 1 gr.

DOSE—1 to 3 Pills.

Pil. Antiseptic Comp. are prescribed with great advantage in cases of Dyspepsia, Indigestion, and Malassimilation of Food.

Supplied upon physician's prescription by all leading druggists.

1228 MARKET ST., Phila. 18 LIBERTY ST., New York.

The Curd of Cow's Milk Made as Soft and Digestible as that of Woman's Milk.

"From experiments which I have recently made — and my thanks are due to Prof. Salisbury of the Woman's Medical College, for assistance — it seems that the claim which is made by the advocates of the MELLIN'S FOOD is true, and that the addition of this food to cow's milk does cause it to break up in very small, flaky curds."— *Dr. Chas. Warrington Earle, Professor of Diseases of Children, Woman's Medical College, Professor of Obstetrics, College Physicians and Surgeons, Chicago, in his paper on Infant Feeding, before the American Medical Association, May, 1888.*

Any physician having a case in which he desires to test MELLIN'S FOOD can obtain a sample sufficient for trial, free of all expense, by application.

DIAMOND MARK.

And insist upon receiving the HUNGARIAN APERIENT WATER of the APOLLINARIS COMPANY, LIMITED, London.

THE VALUE OF NUTRITION IN DISEASE.

All physicians who have ever used Murdock's Liquid Food and Suppositories recognize their value over all other foods, in breaking up disease and building up the patients after disease, preventing a relapse, **as the same results are obtained as in surgery.** Its value in surgical cases we illustrate by the records of the different cities and of Murdock's Free Surgical Hospital for Women, which is the largest in the United States. It contains 114 beds, every bed free, including operation, the operations ranging from 1000 to 1200 yearly, representing 90 of the worst classes known in surgery. Among these cases we have had **Cancer of uterus** (*Kolpo-hysterectomy*), 13; **Salpingitis** (*Tait's operation*), 31; **Fibroid of uterus** (*abdominal hysterectomy*), 19; **Ventral operation, hernia,** (*abdominal section*), 12; **Cancer of bowel** (*incision*), 2; **Parovarian cyst, 6; Papillomatous cyst** (*extirpation*), 4; **Tubercular peritonitis** (*incision*), 1; **Ovarian cystoma 27; Nymphomania** (*Battey*), 1; **Exploratory abdominal incisions, 12; Fibroid with abdominal abscess** (*Hegar*), 2; **Hysterorraphy, 2; Dermoid cyst, 3; Cirrhotic ovaries,** (*Battey*), 4; **Fibroid uterus** (*Hegar*), 6; **Hystero-epilepsy** (*Battey*), 1; **Haemato-Salpinx** (*Tait*), 5; **Rupture of intestine into vagina, 1; Dislocated kidney, 2; Fibroid tumor abdominal wall, 1; Resection of intestine** (*Senn*), 1; **Ruptured perineum, 294.** Patients are in the Hospital 8 days before and 26 days after operation, on an average.

In Boston, last year, 42 deaths were from Cancer in the Breast. In Murdock's Hospital, 35 such cases were operated on without a death, the patients remaining in the Hospital, on an average, 18 days.

Mortality	in Boston,	25.60	per 1000.
"	of Women in Boston,	29,00	" "
"	in **Murdock's Free Surgical Hospital,**	**5.00**	" "
"	New York,	26.32	" "
"	Philadelphia,	20.00	" "
"	Chicago,	20.90	" "
"	St. Louis,	20.49	" "

showing our mortality is only one-sixth as great as of those in health. As good results were obtained in our General Hospital, which we kept open 27 months, **thus showing the value of nutrition as found in Murdock's Liquid Food, and so recognized by the British and American Medical Associations,** before which essays were read and discussed, and it is the only Raw food preparation on which essays were ever read.

Physicians are invited to visit our Hospitals and Works, also to send in patients and to be present at the operations. For any physician who has not used our Liquid Food (and Suppositories for adults and infants), we will deliver free samples to any express company in Boston.

When babies do not thrive, never change their food, but add five or more drops at each feeding of Murdock's Liquid Food, and their lost or needed vitality will be restored in less than thirty days. It is invaluable when weaning babies or when teething. If mothers will take one teaspoonful to a tablespoonful before each meal and on retiring, they will receive as much benefit as the baby.

Murdock Liquid Food Co., Boston.

ALETRIS CORDIAL

UTERINE TONIC AND RESTORATIVE.

Prepared from the Aletris Farinosa or True Unicorn and Aromatics.

INDICATIONS.

Amenorrhea, Dysmenorrhea, Leucorrhea, Prolapsus Uteri, Sterility, to Prevent Miscarriage, Etc.

DOSE:—ONE TEASPOONFUL THREE OR FOUR TIMES A DAY.

UNRIVALED AS A UTERINE TONIC IN IRREGULAR, PAINFUL, SUPPRESSED AND EXCESSIVE MENSTRUATION.

It Restores Normal Action to the Uterus, and Imparts Vigor to the Entire Uterine System.

☞Where women have miscarried during previous pregnancies, or in any case where miscarriage is feared, the ALETRIS CORDIAL is indicated, and should be continuously administered during entire gestation.

CHAS. CLAY, M. R. C. S., Manor House, Dewsbury, England, says:—I find Aletris Cordial (Rio) is of great service in threatened miscarriage.

FRANCIS E. CANE, L. R. C. S., &c., Leeds, England, says:—I have tried the Aletris Cordial (Rio) in two cases of long standing dysmenorrhea, with excellent results. One of these patients has spent a week in bed every month for two years. After all the usual remedies, I put her on Aletris Cordial, and for the last two periods she has been out and about all the time.

L. M. WATSON, M. D., Delhi, Ills., says:—I have used Aletris Cordial (Rio) in cases of dysmenorrhea, suppressed menses and threatened miscarriage, and also, combined with Celerina, as a tonic after confinement, with the happiest results, and now I am using it on a case of leucorrhea, with injections of S. H. Kennedy's Extract of Pinus Canadensis, and it is acting like a charm.

P. H. OWEN, M. D., Morganville, Ala., says:—I have prescribed Aletris Cordial (Rio) in several cases with the most satisfactory results, and regard it as the best uterine tonic I have met with in a professional experience of over twenty-five years. In cases of threatened miscarriage it acts like a charm. Would recommend its continuous administration in all cases when there is any indication of miscarriage.

Dr. W. BERTHELOT, Santander, Spain, says:—I have tried the Aletris Cordial (Rio), and it has seemed to me to be useful, especially in cases of dysmenorrhea.

Dr. RASQUINET, Jupile, near Liege, Belgium, says:—I tried Aletris Cordial (Rio) in the case of a woman who had had several miscarriages at the end of five months, and who is now again pregnant, having reached the seventh month; thanks to Aletris Cordial.

R. REECE, M. R. C. S., Walton-on-Thames, England, says:—Aletris Cordial (Rio) in painful menstruation is most valuable. A wife of a minister suffered much, and had had three miscarriages. I prescribed Aletris Cordial. She has for the first time, gone her full time, and was safely confined with a male child.

J. T. COLLIER, M. D., Brooks, Me., says:—I have used your Aletris Cordial (Rio) in cases of females at the menopause. Consider it one of the finest remedies for these cases.

Dr. GORDILLON, St. Amand, France, says: I have tried the Aletris Cordial (Rio) in a case of dysmenorrhea. The result I obtained from the use of your preparation was excellent, better than I had obtained in the same patient by prescribing the usual remedies employed in such cases.

W. F. TOOMBS, M. D., Morrillton, Ark., says:—I have used a great deal of your Aletris Cordial (Rio) and I find it all you claim for it in amenorrhea, dysmenorrhea, metritis, leucorrhea; I don't think it has an equal. I have used it in two cases of threatened miscarriage and the trouble was obviated. For a general Uterine Tonic I know of nothing superior.

R. D. PATTERSON, L. R. C. S. &c., Medical Officer, Caledon Dispensary, Co. Tyrone, Ireland, says:—I have very great pleasure in testifying to the very high opinion I hold of Aletris Cordial (Rio) in threatened miscarriage.

SPORTING AND ATHLETIC GOODS OF EVERY DESCRIPTION.

No Chemicals.

W. BAKER & CO.'S Breakfast Cocoa

Is Absolutely Pure, and it is Soluble.

To increase the solubility of the powdered cocoa, various expedients are employed, most of them being based upon the action of some alkali, potash, soda or even ammonia. Cocoa which has been prepared by one of these chemical processes, can usually be recognized at once by the distinct alkaline reaction of the infusion in water.

W. Baker & Co.'s Breakfast Cocoa

is manufactured from the first stage to the last by perfect mechanical processes, **no chemical being used in its preparation.** By one of the most ingenious of these mechanical processes the greatest degree of fineness is secured without the sacrifice of the attractive and beautiful red color which is characteristic of an absolutely pure and natural cocoa.

BOUDAULT'S PEPSINE

The only Pepsine used in the Hospitals of Paris for the last Thirty Years.

Unlike the various substitutes which, in most cases, are but unscientific or incompatible compounds, forced upon the Medical Profession as aids to digestion by extensive advertising, but which, when submitted to the proper tests, are found to be useless as digestive agents, Pepsine is constantly gaining in the esteem of the careful practitioner.

Since the introduction of Pepsine by Boudault and Corvisart in 1854, the original BOUDAULT'S PEPSINE HAS BEEN AT ALL TIMES CONSIDERED THE BEST, as is attested by the awards it has received at the Expositions of 1867, 1868, 187 1873, in 1876 at the Centennial Exposition of Philadelphia, and in 1878 at the Paris Exposition.

The most reliable tests, carefully applied, will satisfy everyone that BOUDAULT'S PEPSINE HAS A MUCH HIGHER DIGESTIVE POWER than the best Pepsines now before the Profession, and is therefore especially worthy of their attention.

BOUDAULT'S PEPSINE is prepared in the form of Pepsine Acid and Pepsine Neutral. It is sold in bottles of one ounce, with a measure containing exactly five grains; also in bottles of four, eight, and sixteen ounces for dispensing.

BOUDAULT'S WINE OF PEPSINE

FORMULA OF DR. CORVISART.

The taste of Pepsine being perfectly disguised in this Wine, it may be recommended to persons who have difficulty in taking Pepsine in the form of Powder. This Wine is tested so that a tablespoonful of it is equal in digestive power to ten grains of Boudault's Pepsine in powder. Sold only in bottles of eight ounces.

TANRET'S PELLETIERINE

For the Treatment of Tape-Worm (Tænia Solium).

This New Tænifuge, the Active Alkaloid of Pomegranate Bark, has of late come into extensive use in France for the treatment of Tape-Worm (Tænia Solium). The results of numerous experiments with it at the Marine Hospitals of Toulon, St. Mandrier, etc., and in the Hospitals of Paris, St. Antoine, La Charité, Necker Beaujon, etc., have all been most satisfactory. Doctor Dujardin Beaumetz, Member of the Academy of Medicine, and Professor Laboulbene, in their report to the Society of Therapeutics, have given it their unqualified approval, after the most searching experiments. This preparation is pleasant to administer, and, if certain preliminaries are observed, success will be insured.

Sold only in bottles containing one dose.

DUCRO'S ALIMENTARY ELIXIR

A Combination uniting the properties of Alcoholic Stimulants and Raw Meat.

This preparation, which has been used with great success in the hospitals of Paris since 1868, is adapted to the treatment of all diseases requiring administration, in a small volume, of a tonic able to stimulate and support the vital forces, as *Pulmonar Phthisis, Depression and Nervous Debility, Adynamia, Malarious Cachexia, etc.*

Prepared by EMILE DURIEZ & CO., Successors to DUCRO & CIE, Paris.

KIRKWOOD'S INHALER

This is the only complete, reliable, and effective inhaler in use, arranged for the direct application of Muriate of Ammonia and other remedial agents in the state of vapor to the diseased parts of the air-passages in the treatment of catarrh and diseases of the throat and lungs. No heat or warm liquids required in its use.

It is entirely different from the various frail, cheap instruments that have been introduced.

KIRKWOOD'S INHALER is accompanied by testimonials of the highest professional character, together with carefully prepared formulas for use.

RETAIL PRICE, COMPLETE, $2.50.

☞ A liberal discount allowed to the trade and profession. For descriptive pamphlet or other information address

A Clinical School for Graduates in Medicine and Surgery.

DIRECTORS:

PROF. FORDYCE BARKER, M. D., LL. D.
THOMAS ADDIS EMMET, M. D., LL. D.
PROF. T. GAILLARD THOMAS, M. D.
PROF. ALFRED L. LOOMIS, M. D., LL. D.
LEONARD WEBER, M. D.
HON. EVERETT P. WHEELER.
H. DORMITZER, ESQ.
JULIUS HAMMERSLAUGH, ESQ.
HON. B. F. TRACY.
CHARLES COUDERT, ESQ.
REV. THOMAS ARMITAGE, D. D.
W. A. BUTLER, ESQ.
WILLIAM T. WARDWELL, ESQ.
GEORGE B. GRINNELL, ESQ.
HON. HORACE RUSSELL.
FRANCIS R. RIVES, ESQ.
SAMUEL RIKER, ESQ.

FACULTY:

JAMES R. LEAMING, M.D., Emeritus-Professor of Diseases of the Chest and Physical Diagnosis; Special Consulting Physician in Chest Diseases to St. Luke's Hospital.

EDWARD B. BRONSON, M.D., Professor of Dermatology; Visiting Dermatologist to the Charity Hospital; Consulting Dermatologist to Bellevue Hospital (Out-door Department).

A. G. GERSTER, M.D., Professor of Surgery; Visiting Surgeon to the German and Mt. Sinai Hospitals.

V. P. GIBNEY, M.D., Professor of Orthopædic Surgery; Orthopædic Surgeon to the Nursery and Child's Hospital; Surgeon-in-Chief to the Hospital for Ruptured and Crippled.

LANDON CARTER GRAY, M.D., Professor of Diseases of the Mind and Nervous System; Attending Physician to Hospital for Nervous and Mental Diseases, and to St. Mary's Hospital.

EMIL GRUENING, M.D., Professor of Ophthalmology; Visiting Ophthalmologist to Mt. Sinai Hospital, and to the German Hospital.

*JAMES B. HUNTER, M. D., Professor of Gynæcology; Surgeon to the Woman's Hospital; Surgeon to the New York Cancer Hospital; Consulting Surgeon to the New York Infirmary for Women and Children; President of the Faculty.

PAUL F. MUNDÉ, M.D., Professor of Gynæcology; Gynæcologist to Mt. Sinai Hospital; Consulting Gynæcologist to St. Elizabeth Hospital.

A. R. ROBINSON, M.D., Professor of Dermatology; Professor of Normal and Pathological Histology in the Woman's Medical College.

DAVID WEBSTER M.D., Professor of Ophthalmology; Surgeon to the Manhattan Eye and Ear Hospital.

JOHN A. WYETH, M.D., Professor of Surgery; Visiting Surgeon to Mt. Sinai Hospital; Consulting Surgeon to St. Elizabeth Hospital; Secretary of the Faculty.

W. GILL WYLIE, M D., Professor of Gynæcology; Gynæcologist to Bellevue Hospital.

R. C. M. PAGE, M.D., Professor of General Medicine and Diseases of the Chest; Physician to St. Elizabeth Hospital; Attending Physician to the Northwestern Dispensary, Department of Chest Diseases.

D. BRYSON DELAVAN, M. D., Professor of Laryngology and Rhinology; Laryngologist to the Demilt Dispensary.

JOSEPH WILLIAM GLEITSMANN, M.D., Professor of Laryngology and Rhinology; Laryngologist and Otologist to the German Dispensary.

OREN D. POMEROY, M.D., Professor of Otology; Surgeon Manhattan Eye and Ear Hospital; Ophthalmic Surgeon to New York Infants' Asylum, and Consulting Surgeon to the Paterson Eye and Ear Infirmary.

HENRY N. HEINEMAN, M.D., Professor of General Medicine and Diseases of the Chest; Attending Physician to Mt. Sinai Hospital.

B. SACHS, M.D., Professor of Diseases of the Mind and Nervous System; Consulting Neurologist to the Montefiore Home for Chronic Invalids.

THOMAS R. POOLEY, M.D., Professor of Ophthalmology; Surgeon-in-Chief of the New Amsterdam Eye and Ear Hospital; Ophthalmic Surgeon to the Sheltering Arms; Consulting Ophthalmologist to the St. Bartholomew's Hospital.

L. EMMETT HOLT, M.D., Professor of Diseases of Children; Visiting Physician to the New York Infant Asylum; Consulting Physician to the Hospital for Ruptured and Crippled.

AUGUST SEIBERT, M.D., Professor of Diseases of Children; Physician to the Children's Department of the German Dispensary.

H. MARION SIMS, M.D., Professor of Gynæcology; Gynæcologist to St. Elizabeth Hospital and New York Infant Asylum.

WILLIAM F. FLUHRER, M.D., Professor of Genito-Urinary Surgery; Surgeon to Bellevue and St. Sinai Hospitals.

*Deceased.

THE NEW YORK POLYCLINIC is a School of Clinical Medicine and Surgery for *Practitioners only*. No didactic lectures are given. The classes are limited. The demonstrations are made at the Polyclinic School and Hospital, and in the various Hospitals in New York City with which the Faculty are connected.

Session of 1889-'90 opens Monday, September 16th, 1889. Physicians matriculating for the Winter Session will be admitted to the Clinics from July 1st to September 14th, without additional charge. For further information and for catalogue, address

JOHN A. WYETH, M. D.,
Secretary of the Faculty,
Or WILLIS O. DAVIS, Clerk,
214, 216 & 218 East 34th Street, New York City.

UNIVERSITY OF MARYLAND
SCHOOL OF MEDICINE.

Eighty-third Annual Announcement, 1889-90. The next regular session will begin October 1st, 1889. A full course of didactic lectures, with ample clinical and dissecting-room facilities.

FACULTY:

GEORGE W. MILTENBERGER, M.D.,
Professor of Obstetrics.
CHRISTOPHER JOHNSON, M.D.,
Emeritus Professor of Surgery.
SAMUEL C. CHEW, M.D.,
Professor of Principles and Practice of Medicine and Hygiene.
FRANK DONALDSON, M.D.,
Emeritus Clinical Professor of Diseases of the Throat and Chest.
WILLIAM T. HOWARD, M.D.,
Professor of Diseases of Women and Children and Clinical Medicine.
JULIAN J. CHISOLM, M.D.,
Professor of Eye and Ear Diseases.
FRANCIS T. MILES, M.D.,
Professor of Physiology and Clinical Professor of Diseases of Nervous System.

L. McLANE TIFFANY, M.D.,
Professor of Surgery.
J. EDWIN MICHAEL, M.D.,
Professor of Anatomy and Clinical Surgery.
I. EDMONSON ATKINSON, M.D.,
Professor of Materia Medica and Therapeutics, Clinical Medicine and Dermatology.
R. DORSEY COALE, PH.D.,
Professor of Chemistry and Toxicology.
JOHN NOLAND MACKENZIE, M.D.,
Clinical Professor of Diseases of the Throat and Nose.
HERBERT HARLAN, M.D.,
Demonstrator of Anatomy.

For catalogue and further information, address: **Dr. J. EDWIN MICHAEL, Dean, 937 Madison Avenue.**

DENTAL DEPARTMENT.

Eighth Annual Announcement. Next regular session begins October 1st, 1889. New and excellent Infirmary and Laboratory, with abundance of clinical material.

FACULTY:

FRED. J. S. GORGAS, M.D., D.D.S.,
Professor of Principles of Dental Science, Dental Surgery, and Dental Mechanism.
JAMES H. HARRIS, M.D., D.D.S.,
Professor of Operative and Clinical Dentistry.
I. EDMONSON ATKINSON, M.D.,
Professor of Materia Medica and Therapeutics.
FRANCIS T. MILES, M.D.,
Professor of Physiology.
L. McLANE TIFFANY, M.D.,
Clinical Professor of Oral Surgery.

J. EDWIN MICHAEL, M.D.,
Professor of Anatomy.
R. DORSEY COALE, PH.D.,
Professor of Chemistry.
JOHN C. UHLER, M.D., D.D.S.,
Demonstrator of Mechanical Dentistry.
CHAS. L. STEEL, M.D., D.D.S.,
Demonstrator of Operative Dentistry.
HERBERT HARLAN, M.D.,
Demonstrator of Anatomy.
AND EIGHT ASSISTANT DEMONSTRATORS.

For catalogue and other information, apply to **Dr. F. J. S. GORGAS, Dean, 845 Eutaw Street, Baltimore.**

Medico-Chirurgical College of Philadelphia.

JAS. E. GARRETSON, A.M., M.D., Professor of Oral and Clinical Surgery.
WM. H. PANCOAST, A.M., M.D., Professor of General, Descriptive, and Surgical Anatomy and Clinical Surgery.
GEO. E. STUBBS, A.M., M.D., Professor of Clinical Surgery.
WM. F. WAUGH, A.M., M.D., Professor of Principles and Practice of Medicine and of Clinical Medicine.
ABRAHAM S. GERHARD, A.M., M.D., Professor of Forensic and Clinical Medicine.
WM. S. STEWART, A.M., M.D., Professor of Obstetrics and Clinical Gynecology.
H. EARNEST GOODMAN, M.D., Professor of Principles and Practice of Surgery and Clinical Surgery.
P. D. KEYSER, A.M., M.D., Dean, Professor of Ophthalmology.

SAMUEL B. HOWELL, A.M., M.D., Professor of Chemistry.
JOHN V. SHOEMAKER, A.M., M.D., Professor of Materia Medica, Pharmacology, Therapeutics and Clinical Medicine.
E. E. MONTGOMERY, B.S., M.D., Professor of Gynecology.
JAS. M. ANDERS, Ph.D., M.D., Professor of Hygiene and Clinical Diseases of Children; Associate Professor of Physiology

JOHN V. SHOEMAKER, A.M., M.D., Clinical Professor Skin Diseases.

FRANK WOODBURY, A.M., M.D., Honorary Professor of Clinical Medicine.
WM. B. ATKINSON, A.M., M D. Honorary Professor of Sanitary Science and Paediatrics.

The Regular Session begins September 30th, 1889, and continues until the middle of April. It is preceded by a Preliminary Session of three weeks, and followed by a Spring Session lasting until the middle of June.

Seats are issued in the order of matriculation, and are forfeitable if fees are not paid before November 1st.

Preliminary examination or equivalent degree, and a three years' graded course obligatory. A fourth year voluntary.

Instruction is given by lectures, clinical teaching and practical demonstrations. In the subjects of Anatomy, Pharmacy, Chemistry, Histology and Pathology the usual methods of instruction are largely supplemented by laboratory work.

Examinations are held at the close of each Regular Session upon the studies of the term. Although the degree of Doctor of Medicine is conferred at the end of the third year, a fourth year is earnestly recommended, at the end of which the degree of Doctor of Medicine *cum laude* is given.

FEES.

Matriculation, $5; first and second years, each, $100; third year (no graduation fee), $100; fourth year, free to those who have attended three sessions in this school, to all others, $100.

Extra charges only for material used in the laboratories and dissecting-room.

For further information or announcement, address,

E. E. MONTGOMERY, M.D., Secretary,
Medico-Chirurgical College,
Cherry, below 18th Street, Philadelphia, Penna.

Medical College of Ohio.

Medical Department of the University of Cincinnati.

The Seventy-first Annual Session will begin September 4, 1889, and continue until March 1, 1890.

FEES.—Matriculation Ticket, $5.00; General Lecture Ticket, $75.00; Hospital Ticket, $5.00; Graduation Fee, $25.00.

For circulars, and further information, address
JAMES G. HYNDMAN, M.D., Secretary,
22 West Ninth Street, Cincinnati, Ohio.

WESTERN PENNSYLVANIA MEDICAL COLLEGE

CITY OF PITTSBURGH.

SESSIONS OF 1889—90.

The REGULAR SESSION begins on the last Tuesday of September, and continues six months. During this session, in addition to four Didactic Lectures, two or three hours are daily allotted to Clinical Instruction. Attendance upon two regular courses of lectures is requisite for graduation. A three years' graded course is also provided. The SPRING SESSION embraces recitations, clinical lectures and exercises, and didactic lectures on special subjects; this session begins the second Tuesday in April, and continues ten weeks.

The laboratories are open during the collegiate year for instruction in chemistry, microscopy, practical demonstrations in medical and surgical pathology, and lessons in normal histology. Special importance attaches to "the superior clinical advantages possessed by this College." For particulars, see annual announcement and catalogue, for which, address the Secretary of Faculty, Prof. J. W. J. McKENNAN.

Business correspondence should be addressed to
PROF. W. J. ASDALE, 2107 Penn Avenue, Pittsburgh.

Woman's Medical College
OF BALTIMORE.

S. E. Cor. Druid Hill Ave. and Hoffman St., Baltimore, Md.

THE EIGHTH ANNUAL SESSION WILL BEGIN ON WEDNESDAY, OCTOBER 2d, 1889.

For further information or catalogue, address
RANDOLPH WINSLOW, M.D., Acting Dean,
No. 1, Mount Royal Terrace, Baltimore, Md.

Medical Department, State University of Iowa, at Iowa City, Iowa.

The next Session will begin on September 11, 1889, and continue until March 12, 1890. Attendance upon three courses of lectures, of six months each, is requisite to graduation. The facilities for dissection and clinical study are unsurpassed.

TERM EXPENSES—Lecture Ticket, $20.00; Demonstrator's Ticket, $10.00; Matriculation Ticket, $5.00 (paid but once); Hospital Ticket, $3.00; Examination Fee (for final examination) $25.00. No charge for dissecting material. For further information, address DR. A. C. PETERS, Ast. Sec'y, Iowa City, Iowa.

Medical and Surgical History of the War.

The widow of a physician will sell CHEAP the six volumes of Medical and Surgical History of the War of the Rebellion. In good condition. Address,
MRS. D. M., care of MED. & SURG. REPORTER,
P. O. Box 843. Philadelphia.

DETROIT COLLEGE OF MEDICINE.

SESSION 1889-90.

Clinical and Practical teaching are made an important feature of this College. Clinical instruction is given daily at HARPER, ST. MARY'S and ST. LUKE'S HOSPITAL, at the COLLEGE, at COLLEGE EYE and EAR INFIRMARY, ST. MARY'S FREE EYE and EAR INFIRMARY, and at the three FREE DISPENSARIES. The facilities offered by this college are unsurpassed for the practical study of MEDICINE, SURGERY, OBSTETRICS, GYNÆCOLOGY, DISEASES OF CHILDREN, GENITO-URINARY, and ORTHOPÆDIC SURGERY, OPHTHALMOLOGY and OTOLOGY, DERMATOLOGY and LARYNGOLOGY.

REGULAR SESSION opens on Wednesday, Sept. 25, and continues six months. During the session, the Professors will take special pains to examine the Students upon the subjects of the previous lectures.

SPRING SESSION begins April 2d, 1890; and closes June 11th.

FEES.—Matriculation fee, $5; Fees for Regular Session, $50; Spring Session, $10, to those who attend the regular term—to all others, $25; Hospital Fee, $10; Graduation Fee, $30; Perpetual Ticket, $100.

For further particulars, and for College Circular, apply to

H. O. WALKER, M.D., Secretary,
33 Lafayette Ave., Detroit, Mich.

UNIVERSITY OF PENNSYLVANIA.—Medical Department.

The 124TH ANNUAL WINTER SESSION will begin Tuesday, October 1st, 1889, at 12 M., and continue until May 1st, 1890.
The PRELIMINARY SESSION begins September 18th, 1889.
The curriculum is graded and three annual winter sessions are required. Practical instruction, including laboratory work in Chemistry, Histology, Osteology and Pathology, with Bedside Instruction in Medicine, Surgery and Gynecology are a part of the regular course and without additional expense.

FACULTY.

JOSEPH LEIDY, M.D., LL.D., Professor of Anatomy.
D. HAYES AGNEW, M.D, LL.D., Honorary Professor of Clinical Surgery.
WILLIAM PEPPER, M.D., LL.D., Professor of Theory and Practice of Medicine, and of Clinical Medicine.
WILLIAM GOODELL, M.D., Professor of Gynecology.
JAMES TYSON, M.D., Professor of Clinical Medicine.
HORATIO C. WOOD, M.D., LL.D, Professor of Materia Medica, Pharmacy and General Therapeutics.
THEODORE G. WORMLEY, M.D., LL.D., Professor of Chemistry and Toxicology.
JOHN ASHHURST, JR., M.D., Professor of Surgery and of Clinical Surgery.
EDWARD T. REICHERT, M.D., Professor of Physiology.
WILLIAM F. NORRIS, M.D., Honorary Prof. of Ophthalmology
BARTON COOKE HIRST, M.D., } Associate Professors of
HOWARD A. KELLY, M.D., } Obstetrics.
J. WILLIAM WHITE, M.D., Professor of Clinical Surgery.
JOHN GUITÉRAS, M.D., Professor of General Pathology and Morbid Anatomy.
GEORGE A. PIERSOL, M.D., Professor of Histology and Embryology.
SAMUEL G. DIXON, M.D., Professor of Hygiene.

BUFFALO LITHIA WATER

IN THE

Uric Acid Diathesis, Bright's Disease of the Kidneys, Chronic Inflammation of the Bladder, &c.

Dr. THOMAS H. BUCKLER, of Paris (formerly of Baltimore), SUGGESTER OF LITHIA as a Solvent for URIC ACID.

"Nothing I could say would add to the **WELL-KNOWN REPUTATION OF THE BUFFALO LITHIA WATER. I HAVE FREQUENTLY USED IT WITH GOOD RESULTS IN URIC ACID DIATHESIS, RHEUMATISM AND GOUT,** and with this object I have ordered it to Europe from Coleman & Rogers, of Baltimore. Lithia is in no form so valuable as where it exists in the Carbonate (the form in which it is found in the **BUFFALO LITHIA WATER**), Nature's modé of solution and division in water which has passed through Lepedolite and Spondumine Mineral formation."

Dr. WM. A. HAMMOND, of New York, Surgeon-General U. S. Army (Retired), Professor of Diseases of the Mind and Nervous System in the University of New York, &c.

"I have for some time made use of the Buffalo Lithia Water in cases of affections of the **NERVOUS SYSTEM,** complicated with **BRIGHT'S DISEASE OF THE KIDNEYS** or with a **GOUTY DIATHESIS.** The results have been eminently satisfactory. Lithia has for many years been a favorite remedy with me in like cases, but the **BUFFALO WATER CERTAINLY ACTS BETTER THAN ANY EXTEMPORANEOUS SOLUTION OF THE LITHIA SALTS,** and is, moreover, better borne by the Stomach. I also often prescribe it in those cases of **CEREBRAL HYPERÆMIA** resulting from over-mental work—in which the condition called **NERVOUS DYSPEPSIA EXISTS**—and generally with marked benefit."

HUNTER McGUIRE, M.D., LL.D., Late Professor of Surgery, Medical College of Virginia, Richmond.

"**BUFFALO LITHIA WATER,** *Spring No. 2,* as an **ALKALINE DIURETIC,** *is invaluable.* In **URIC ACID GRAVEL,** *and, indeed,* in *diseases generally dependent* upon a **URIC ACID DIATHESIS,** *it is a remedy of extraordinary potency.* I have prescribed it in cases of **RHEUMATIC GOUT,** *which had resisted the ordinary remedies, with wonderful good results.* I have *used it also in my own case, being a great sufferer from this malady, and have derived more benefit from it than from any other remedy.*"

Dr. ROBERT BATTEY, of Georgia, SUGGESTER OF BATTEY'S OPERATION.

"I would state that I have been using the Buffalo Lithia Water, No. 2, in my practice for three years past, in cases of **CHRONIC INFLAMMATION** of the **BLADDER,** whether induced by **STONE,** by enlarged **PROSTATE** in the aged, or by **NEGLECTED GONORRHŒA, AND HAVE SECURED EXCELLENT RESULTS,** which encourages me to prescribe it for the future."

Dr. CYRUS EDSON, of New York,
Chief Inspector of Cutaneous Diseases in Health Department and President of the Board of Pharmacy.

"I have frequently made use of **BUFFALO LITHIA WATER,** Spring No. 2, in my practice, *with excellent results.* It is a potent remedy in correcting **RHEUMATIC DIATHESIS.** In a case of **URIC ACID GRAVEL,** in which I recently prescribed it, **ITS BENEFICIAL EFFECTS WERE APPARENT AFTER THE THIRD DOSE.** I have also prescribed it with great benefit in **BRIGHT'S DISEASE OF THE KIDNEYS.**"

Water in Cases of one dozen half-gallon Bottles, Five Dollars per Case, at the Springs.

THOMAS F. GOODE,

PROPRIETOR,

BUFFALO LITHIA SPRINGS,

VIRGINIA.

BUFFALO LITHIA WATER

IN THE TREATMENT OF CHRONIC GASTRIC CATARRH

CLINICAL REPORTS.

CHRONIC GASTRIC CATARRH AND URIC ACID CALCULI.

A case stated by Dr. JNO. C. COLEMAN, of Scottsburg, Va., a retired Surgeon of the U. S. Navy.

"Mr. C. was for a number of years a sufferer from **CHRONIC GASTRIC CATARRH.** While his diet *was exclusively* **TEA** and **CRACKERS, BREAD** and **MILK,** *and other similar articles*, it was frequently thrown off in an undigested state soon after taking it, and at times he discharged from an empty stomach a strongly acid glairy mucus. A marked **URIC ACID DIATHESIS** supervened, consequent upon which he suffered for a period of some two years great **VESICAL IRRITATION** and possible **CYSTITIS,** attended by pain so intense and constantly present, as to require that he should be kept for the most part under the influence of opiates. After a persistent, but ineffectual exhibition of all remedies supposed to be indicated in the case, he was put for the latter affection upon the **BUFFALO LITHIA WATER,** Spring No. 2, with the happiest possible effect.

"In a few weeks, after commencing the use of it, the irritable condition of the *Bladder* was so far relieved that he was enabled to dispense entirely with the use of opiates. At the expiration of some eight weeks he had an attack of unusual severity, from which he was relieved by the discharge of a **CALCULUS,** followed at short intervals by the discharge of three others, which proved to be the termination of this trouble, as from that time there was entire subsidence of the painful symptoms described, and the *Bladder* resumed its natural state.

"While prescribed with special reference to the relief of the *Irritable Bladder*, the action of the water was not less surprisingly happy in the **GASTRIC AFFECTION,** with remarkable promptness correcting the highly acid condition of the **STOMACH,** restoring a healthy digestion and assimilation, and *tone* and *vigor* to the depressed *Nervous System.*

"In a few months he was able to eat, with perfect impunity, the coarsest articles of diet. He is now, after a lapse of several years, in robust health, having had no return of these painful maladies."

CHRONIC GASTRIC CATARRH.

Case of JOHN P. KEELING, Esq., stated by Dr. S. S. KEELING, Norfolk, Va., Member Medical Society of Virginia.

"Mr. John P. Keeling labored under **CHRONIC DYSPEPSIA,** and was always subject to attacks of *Spasmodic Gastralgia* immediately upon taking food into the stomach, which attacks were not at all amenable to treatment. Not unfrequently the stomach *rejected everything in the way of food and drink*, and he was of necessity confined to the lightest possible articles of diet, *meat and vegetables being entirely excluded.* He became so prostrated that it was with difficulty he could walk across his chamber floor, and had often to be lifted about. Such was the state of his **NERVOUS SYSTEM** *that great solicitude was felt as to his mental condition.*

"He visited Baltimore for medical aid, and was for many months under the treatment of some of the most eminent men of the profession in that city, but without beneficial result, and was finally advised that he had nothing to hope from remedies.

"Returning in an extremely critical condition to his home in the county of Princess Anne, he came under my professional care. Satisfied that medicine was unavailing in the case, I advised the **BUFFALO LITHIA WATER,** Spring No. 2. His stomach, however, was in a highly irritable condition, and I found it necessary to administer it in very small quantities; and it was at first given not exceeding an ounce at a dose, repeated at stated intervals. At the expiration of the third day the irritability of the stomach was decidedly less, and the quantity was then increased from day to day until the thirteenth day, when I found that the patient could take twelve ounces, which I regard as maximum dose at any time. Persisting in its use, on the twenty-eighth day he was free from pain, the stomach in a normal condition readily receiving both solids and liquids in moderate quantities, strength greatly increased, and nervous symptoms entirely relieved. At the expiration of the seventh week he was able to attend actively and regularly to his business on the farm. His recovery, which I regard as one of the most remarkable I ever knew of, I attribute entirely to the **BUFFALO LITHIA WATER."**

GASTRO-INTESTINAL CATARRH.

Case of Mrs. Dr. F. J. GREGORY, of Virginia, reported by F. J. GREGORY, M.D., Keysville, Va.

"For eighteen months my wife, aged forty-one years, was a sufferer from a **GASTRO-INTESTINAL CATARRH,** which resisted my best-directed efforts at relief. The taking of the smallest quantity of the most easily-digested food on the stomach would produce an attack of *nausea and vomiting, the severity of which is seldom witnessed*, and when the stomach was free of food she would have attacks of *Gastralgia of the most excruciating nature.* She also suffered from habitual constipation, and at times with hemorrhages from the bowels. I pursued the usual line of treatment, such as simple bitters, Dilute Hydrocyanic Acid, Bismuth, etc., and called to my help two of the most skilled physicians in Southside Virginia, who supplemented my treatment with some of the newer drugs, such as **EFFERVESCING BICARB. POTASS. LACTOPEPTINE, CARLSBAD MINERAL SALTS,** etc., but with no benefit, and so her condition went on from bad to worse *until death seemed almost imminent from inanition.* I then put her on a milk diet with a glass of **BUFFALO LITHIA WATER,** Spring No. 2, every hour or so during the day, and *after the use of the first bottle improvement was marked, and before a case of it was used I regarded her cure as complete.* It has been nearly two years since, and there has been only one slight recurrence, which was a few days since, and it readily disappeared on the use of the water for a few days."

Water in cases of one dozen half-gallon bottles, $5 per case, at the Springs.

THOMAS F. GOODE, Proprietor,

BUFFALO LITHIA SPRINGS, VIRGINIA.

THE NEW HYPNOTIC
SULFONAL-BAYER.

SULFONAL was discovered by Prof. Eugen A. Baumann, of Freiburg University, and was first prepared by the Farbenfabriken vorm. Friedr. Bayer & Co., Elberfeld.

SULFONAL (Diæthylsulfondimethylmethan) is in the form of colorless prisms, odorless, and tasteless, melting at 125.5° C. (258° F.) and has the composition $(C H_3)_2=C=(C_2 H_5 SO_2)_2$. It is slightly soluble in cold water, but easily soluble in hot water or alcohol.

SULFONAL was first examined as to its physiological and pathological effects by Prof. A. Kast, of Freiburg University, and its hypnotic action was discovered and studied by him.

Since then SULFONAL has been the subject of numerous trials and experiments by many eminent and experienced physicians. Their testimony is unanimously favorable, and the conclusions reached by them are as follows:

SULFONAL is a prompt and reliable hypnotic, which in proper doses, produces quiet, natural sleep, lasting a number of hours.

SULFONAL has no unfavorable effects on the heart and the circulation, nor on the temperature, the pulse, or the respiration.

SULFONAL produces no disagreeable secondary symptoms; the patients with very few exceptions awake from their sleep feeling strong and greatly refreshed.

SULFONAL does not interfere with the process of digestion.

SULFONAL is a hypnotic, and not a narcotic; it acts by giving rest to the cells of the cerebral cortex, thereby causing sleep.

SULFONAL does not create an unconquerable desire for its repeated use; there is no danger of a SULFONAL-habit. Neither is it necessary to increase the dose after long-continued use.

SULFONAL is best administered at supper-time, dissolved in hot liquids, *e. g.*, a bowl of soup or broth, a cup of milk, tea, coffee, cocoa, etc.

These points will be found to be fully exhibited in the series of contributions contained in our pamphlet, which will be mailed on application.

SULFONAL-BAYER is supplied by us in half-ounce and one-ounce vials.

We prepare 5-grain and 15-grain Tablets of Sulfonal-Bayer. The tablet form is admirably adapted to the purpose of administering this drug, as when they are placed in the liquids, they disintegrate and are thus received into the system.

We also put up Sulfonal-Bayer in the form of our Soluble Pills, containing five grains each.

THE NEW ANTIPYRETIC
PHENACETINE-BAYER.

Phenacetine-Bayer (Para-Acetphenetidine) is a white, glossy, crystalline powder, perfectly tasteless, melting at 135° C.=307° F and has the composition $C_6 H_4 <^{O.C_2H_5}_{NH(CO—CH_3)}$.

It is slightly soluble in water, a little more soluble in glycerine, but most freely in alcohol.

Phenacetine-Bayer was first prepared by the Farbenfabriken, formerly Friedr. Bayer & Co., Elberfeld, and is of absolute purity and uniform quality.

Summarizing the superiority of Phenacetine-Bayer over other antipyretics and antineuralgics, the following conclusions are formed:

1. ***Phenacetine-Bayer is an efficacious antipyretic.***
2. ***It does not develop any disagreeable or noxious after-effects.***
3. ***The dose required is half that of Antipyrine.***
4. ***It is perfectly tasteless.***
5. ***On account of its innocuousness and tastelessness, it is a valuable antipyretic both in adults and in children.***
6. ***Phenacetine-Bayer is an important antineuralgic; its effect is more energetic than that of Antipyrine and does not cause lassitude or any other disagreeble symptoms.***

Our pamphlet on Phenacetine-Bayer, containing the valuable testimony of eminent physicians will be mailed on application.

We offer Phenacetine-Bayer in one-ounce vials, or in the form of our Soluble Pills of the strength of two and four grains to each pill.

RABUTEAU'S DRAGEES OF IRON

Laureate of the Institute of France.—Prize in Therapeutics.

The studies made by the Physicians of the Hospitals have demonstrated that the **Genuine Dragees of Iron of Rabuteau** are superior to all other preparations of Iron in cases of *Chlorosis, Anæmia, Leucorrhœa, Debility, Exhaustion, Convalescence, Weakness of Children,* and the maladies caused by the Impoverishment and Alteration of the blood after periods of fatigue, watching, and excesses of any kind.

TAKE 4 TO 6 DRAGEES DAILY.

Rabuteau's Elixir of Iron is recommended to those persons who may be unable to swallow the Dragees. Dose —*A small wineglassful with meals.*

Rabuteau's Syrup of Iron is specially designed for children. Chalybeate medication, by means of **Rabuteau's Iron,** is the most economical and the most rational known to therapeutics.

No constipation, no diarrhœa, complete assimilation.

Take only the GENUINE IRON OF RABUTEAU of

CLIN & CO., Paris.

SOLUTION OF THE SALICYLATE OF SODA OF DOCTOR CLIN.

Laureate of the Paris Faculty of Medicine (MONTYON PRIZE).

Dr. Clin's Solution, always identical in its composition, and of an agreeable taste, permits the easy administration of *pure Salicylate of Soda,* and the variation of the dose in accordance with the indications presented.

"The *Salicylate of Soda* used by **Clin** is of perfect purity, "and is prepared with the greatest care; it is a medicament "in which we may have every confidence."

—*Paris Society of Medicine, Meeting of Feb. 8th, 1879.*

Clin's Solution, very exactly mixed, contains: 2 grammes of *Salicylate of Soda* per tablespoonful, 50 centigrammes of *Salicylate of Soda* per teaspoonful.

GRAND NATIONAL PRIZE OF 16,600 FRANCS,

QUINA-LAROCHE

This meritorious **Elixir, QUINA-LAROCHE,** is prepared from the **three** Cinchonas; it is an agreeable and doubtless highly efficacious remedy.

—*The Lancet.*

VINOUS ELIXIR,

A STIMULATING RESTORATIVE

—AND—

ANTI-FEBRILE TONIC.

QUINA-LAROCHE under the form of a vinous **Elixir** contains the totality of the numerous principles of the **three** Cinchona barks. It is a preparation which renders great services to Therapeutics.—Extract of the *Gazette des Hôpitaux,* Paris.

FAR SUPERIOR TO ALL ORDINARY CINCHONA WINES.

LAROCHE'S QUINA, tried by the Academy of Medicine of Paris, is a specially prepared COMPOUND EXTRACT of Quinquina, a careful analysis, confirmed by experience, has shown that most of the wines and syrups hitherto used have not contained all the properties of this precious bark, of these some, although beneficial, are altogether lost, while many preparations contain but half the properties of the bark in varying proportions.

MR. LAROCHE, by his peculiar method, has succeeded in extracting all the active principles of the quinquina, combining these with *Catalan Wine* forming an Elixir free from the disagreeable bitterness of other similar preparations. Practitioners have found triple advantages in the use of this Elixir, it is a *strong tonic,* is easily administered, and perfectly harmless, being free from the unpleasant effects of Quinine.

THE FERRUGINOUS QUINA-LAROCHE is the invigorating tonic *par excellence,* having the advantage of being easily assimilated by the gastric juice; without, in any way, deranging the action of the digestive organs, proving itself to be a most efficacious remedy in cases of impoverishment of the blood, ANÆMIA, CHLOROSIS, INTESTINAL HÆMORRHAGE, CASTRALGIA, EXHAUSTION, ETC., ETC.

BROMIDIA

THE HYPNOTIC.

FORMULA.—

Every fluid drachm contains 15 grains EACH of Pure Chloral Hydrat. and purified Brom. Pot., and one-eighth grain EACH of gen. imp. ext. Cannabis Ind. and Hyoscyam.

DOSE.—

One-half to one fluid drachm in WATER or SYRUP every hour, until sleep is produced.

INDICATIONS.—

Sleeplessness, Nervousness, Neuralgia, Headache, Convulsions, Colic, Mania, Epilepsy, Irritability, etc. In the restlessness and delirium of fevers it is absolutely invaluable.

IT DOES NOT LOCK UP THE SECRETIONS.

PAPINE

THE ANODYNE.

Papine is the Anodyne or pain-relieving principle of Opium, the Narcotic and Convulsive Elements being eliminated. It has less tendency to cause Nausea, Vomiting, Constipation, Etc.

INDICATIONS.—

Same as Opium or Morphia.

DOSE.—

(ONE FLUID DRACHM)—represents the Anodyne principle of one-eighth grain of Morphia.

IODIA

The Alterative and Uterine Tonic.

FORMULA.—

Iodia is a combination of active principles obtained from the Green Roots of Stillingia, Helonias, Saxifraga, Menispermum, and Aromatics. Each fluid drachm also contains five grains Iod. Potas., and three grains Phos. Iron.

DOSE.—

One or two fluid drachms (more or less as indicated) three times a day before meals.

INDICATIONS.—

Syphilitic, Scrofulous and Cutaneous Diseases, Dysmenorrhea, Menorrhagia, Leucorrhea, Amenorrhea, Impaired Vitality, Habitual Abortions, and General Uterine Debility.

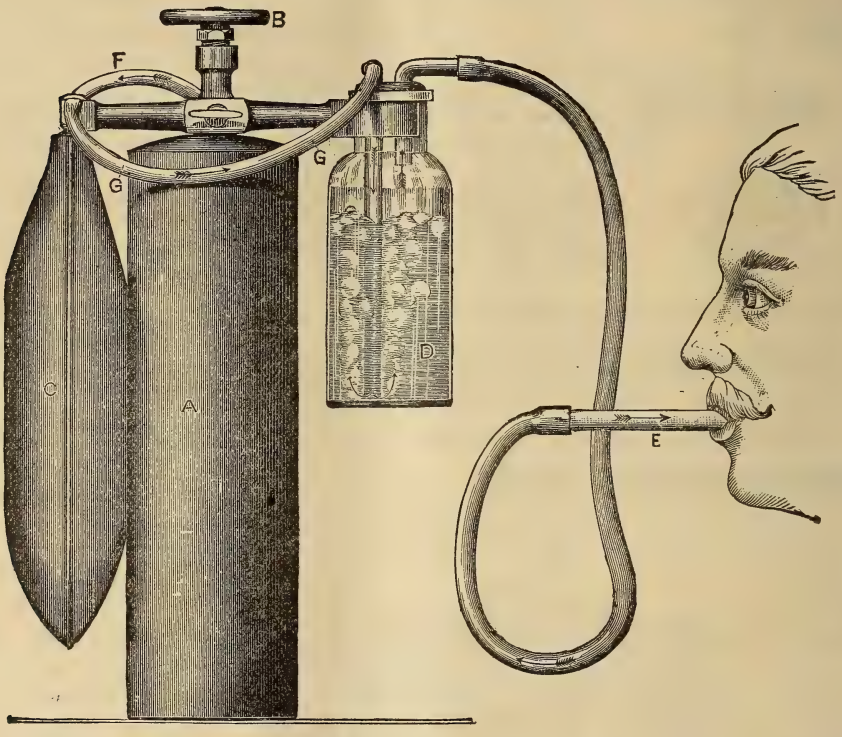
INHALATION APPARATUS

FOR

THE THERAPEUTIC ADMINISTRATION OF OXYGEN.



In the treatment of lung troubles by Oxygen its exhibition by inhalation is preferred. The apparatus herewith shown is a modification of the Nitrous Oxide apparatus which we have supplied for many years. It is made in the best manner throughout, and is the outcome of years of experience in the manufacture of gas apparatus. It will be found to meet all the requirements.

We supply the gas in two sizes of cylinders, containing respectively forty and one hundred gallons, either pure Oxygen, or a mixture of Oxygen and Nitrous Oxide in definite proportions of 20 per cent., and forty per cent. of Nitrous Oxide.

Whether pure or mixed the gas is sold at the uniform price of 5 cents a gallon. The cost of the cylinders will be refunded on their return empty with the valves in good condition. Full description of Inhalation and Enema apparatuses with directions for use accompany each apparatus, or will be supplied on application.

PRICES.

Inhalation Apparatus	$5.00
Cylinder, 40 gallons' capacity	6.00
40 gallons Gas, either pure Oxygen or mixed Oxygen and Nitrous Oxide	2.00
Complete Apparatus, Cylinder, and 40 gallons Gas	$13.00
Inhalation Apparatus	$5.00
Cylinder, 100 gallons' capacity	15.00
100 gallons Gas, either pure or mixed	5.00
Complete Apparatus, Cylinder, and 100 gallons Gas	$25.00

THE BEST ANTISEPTIC
FOR BOTH INTERNAL AND EXTERNAL USE.

ANTISEPTIC, PROPHYLACTIC, DEODORANT.

LISTERINE

NON-TOXIC, NON-IRRITANT, NON-ESCHAROTIC.

FORMULA—Listerine is the essential antiseptic constituent of Thyme, Eucalyptus, Baptisia, Gaultheria and Mentha Arvensis, in combination. Each fluid drachm also contains two grains of refined and purified Benzo-boracic Acid.

DOSE—Internally: One teaspoonful three or more times a day (as indicated) either full strength, or diluted, as necessary for varied conditions.

LISTERINE is a well-proven antiseptic agent—an antizymotic—especially adapted to internal use, and to make and maintain surgical cleanliness—asepsis—in the treatment of all parts of the human body, whether by spray, irrigation, atomization, or simple local application, and therefore characterized by its particular adaptability to the field of

PREVENTIVE MEDICINE—INDIVIDUAL PROPHYLAXIS.

Diseases of the Uric Acid Diathesis.

LAMBERT'S

LITHIATED HYDRANGEA

KIDNEY ALTERATIVE—ANTI-LITHIC.

FORMULA—Each fluid drachm of "Lithiated Hydrangea" represents thirty grains of FRESH HYDRANGEA and three grains of CHEMICALLY PURE Benzo-Salicylate of Lithia. Prepared by our improved process of osmosis, it is INVARIABLY of DEFINITE and UNIFORM therapeutic strength, and hence can be depended upon in clinical practice.

DOSE—One or two teaspoonfuls four times a day (preferably between meals).

Urinary Calculus, Gout, Rheumatism, Bright's Disease, Diabetes, Cystitis, Hæmaturia Albuminuria, and Vesical irritations generally.

We have much valuable literature upon { GENERAL ANTISEPTIC TREATMENT, LITHEMIA, DIABETES, CYSTITIS, ETC. } To forward to Physicians upon request:

LAMBERT PHARMACAL CO., ST. LOUIS, MO.

CALIFORNIA VINTAGE CO.

21 PARK PLACE N.Y.

Geo Hamlin Pres't. Chas Roome Parmele Treas.

GENTLEMEN:

The Case of your wines sent me for analysis by Dr. A. L. Hummel, of the "Annals of Hygiene," containing specimens of your La Rosa Zinfandel, Mataro, Riesling, Royal Tokay, and Royal Grape Brandy, has been duly received.

I have examined them for the common contaminants of wine; to wit: Sulphurous acid and sulphites, salicylic acid, fuchsin, lead salts, etc., none of which I found present therein.

I have also determined their alcoholic strength, extractives, and ashes, and found them to correspond strictly in this respect with the standard of pure and natural wines, which cannot be said of many of the imported wines.

As a native of a wine-producing country, I consider myself somewhat of a judge of wines, and regard your products as comparing more than favorably with most of the wines from abroad which are sold at higher prices, so much so that I enclose within my order for fifty bottles of La Rosa Zinfandel, which I expect to use hereafter exclusively at my table.

Very Respectfully,

L. WOLFF, M.D.,
Demonstrator of Chemistry, Jefferson Medical College.

McARTHUR'S SYRUP.

(SYR: HYPOPHOS: COMP: C. P. McARTHUR.)

Its use is indicated in Consumption and Tuberculosis, Diseases of the Chest, Chronic Cough, Throat Affections, General Debility, Brain Exhaustion, Impotence and Loss of Memory.

The point of primary importance in the use of the Hypophosphites is their *chemical* purity, but unfortunately they are too often adulterated.

So little seems to be generally known, even among the medical profession, with regard to the chemistry of the Hypophosphites, and the absolute necessity of CHEMICAL purity, that we call attention to this point.

One of the first effects produced by the use of our CHEMICALLY PURE Hypophosphites is a general increase of nervous energy, with a feeling of ease and comfort.

The second effect is an increase of appetite; digestion is improved, and the bowels become regular in their action, the quantity and color of the blood is increased, respiration is controlled, a better expansion of the chest is observed, cough improves, easy expectoration is produced, night perspiration diminishes, the face becomes fuller, the lips red, the nails and hair grow, and in children the teeth, showing the importance of the Hypophosphites on the organ of nutrition.

☞ Physicians when prescribing will please write thus:

℞ SYR: HYPOPHOS: COMP: McARTHUR. ONE BOTTLE.

As it is made *only for physicians* there are no printed wrappers or advertisements about the bottle.

Our pamphlet on the **CURABILITY AND TREATMENT OF CONSUMPTION,** sent free to physicians upon application.

We will send one bottle of McArthur's Syrup to any physician, without charge, who will pay the express charges on the same.

Mention this Journal. McARTHUR HYPOPHOSPHITE CO., BOSTON, MASS.

Intestinal Diseases of Children.

"In Cholera Infantum," says Dr. Louis Starr, "the irritability of the stomach is a formidable barrier to alimentation; nevertheless, every effort must be made to give food in small quantities and at short intervals." Clinical experience, the only conclusive test, has proved the great efficacy in this disease, of MELLIN'S FOOD dissolved in water only and given cold, in small amount frequently repeated. "In MELLIN'S FOOD," says Dr. Eustace Smith, "the whole of the starch is converted into dextrine and grape sugar (properly maltose) so that the greater part of the work of digestion is performed before the food reaches the child's stomach." He also says, "I have never seen any signs of fermentation which I could attribute to the influence of maltose." As it is non-fermentable and so quickly assimilated, MELLIN'S FOOD is the best food for infants suffering from this complaint until convalescence has been sufficiently established to allow the regular diet to be resumed.

A sample of MELLIN'S FOOD will be sent to any physician, free of all expense, upon application.

And insist upon receiving the HUNGARIAN APERIENT WATER of the APOLLINARIS COMPANY, LIMITED, London.

THE VALUE OF NUTRITION IN DISEASE.

All physicians who have ever used Murdock's Liquid Food and Suppositories recognize their value over all other foods, in breaking up disease and building up the patients after disease, preventing a relapse, **as the same results are obtained as in surgery.** Its value in surgical cases we illustrate by the records of the different cities and of Murdock's Free Surgical Hospital for Women, which is the largest in the United States. It contains 114 beds, every bed free, including operation, the operations ranging from 1000 to 1200 yearly, representing 90 of the worst classes known in surgery. Among these cases we have had **Cancer of uterus** (*Kolpo-hysterectomy*), 13; **Salpingitis** (*Tait's operation*), 31; **Fibroid of uterus** (*abdominal hysterectomy*), 19; **Ventral operation, hernia,** (*abdominal section*), 12; **Cancer of bowel** (*incision*), 2; **Parovarian cyst, 6; Papillomatous cyst** (*extirpation*), 4; **Tubercular peritonitis** (*incision*), 1, **Ovarian cystoma 27; Nymphomania** (*Battey*), 1; **Exploratory abdominal incisions, 12; Fibroid with abdominal abscess** (*Hegar*), 2; **Hysterorraphy, 2; Dermoid cyst, 3; Cirrhotic ovaries,** (*Battey*), 4; **Fibroid uterus** (*Hegar*), 6; **Hystero-epilepsy** (*Battey*), 1; **Haemato-Salpinx** (*Tait*), 5; **Rupture of intestine into vagina, 1; Dislocated kidney, 2; Fibroid tumor abdominal wall, 1; Resection of intestine** (*Senn*), 1; **Ruptured perineum, 294.** Patients are in the Hospital 8 days before and 26 days after operation, on an average.

In Boston, last year, 42 deaths were from Cancer in the Breast. In Murdock's Hospital, 35 such cases were operated on without a death, the patients remaining in the Hospital, on an average, 18 days.

Mortality in Boston,	25.60	per 1000.
" of Women in Boston,	29,00	" "
" in **Murdock's Free Surgical Hospital,**	**5.00**	" "
" New York,	26.32	" "
" Philadelphia,	20.00	" "
" Chicago,	20.90	" "
" St. Louis,	20.49	" "

showing our mortality is only one-sixth as great as of those in health. As good results were obtained in our General Hospital, which we kept open 27 months, **thus showing the value of nutrition as found in Murdock's Liquid Food, and so recognized by the British and American Medical Associations,** before which essays were read and discussed, and it is the only Raw food preparation on which essays were ever read.

Physicians are invited to visit our Hospitals and Works, also to send in patients and to be present at the operations. For any physician who has not used our Liquid Food (and Suppositories for adults and infants), we will deliver free samples to any express company in Boston.

When babies do not thrive, never change their food, but add five or more drops at each feeding of Murdock's Liquid Food, and their lost or needed vitality will be restored in less than thirty days. It is invaluable when weaning babies or when teething. If mothers will take one teaspoonful to a tablespoonful before each meal and on retiring, they will receive as much benefit as the baby.

Murdock Liquid Food Co., Boston.

CELERINA

NERVE TONIC, STIMULANT AND ANTISPASMODIC.

FORMULA.—Every Fluid Drachm represents FIVE grains EACH—Celery, Coca, Kola, Viburnum and Aromatics.

INDICATIONS.—Loss of Nerve-Power (so usual with Lawyers, Preachers, Writers and Business Men), Impotency, Spermatorrhea, Nervous Headache, Neuralgia, Paralysis, Hysteria, Opium Habit, Inebriety, Dyspepsia, and ALL LANGUID conditions of the System.

Indispensable to restore a patient after alcoholic excess.

DOSE.—One or two Teaspoonfuls three or more times a day, as directed by the Physician.

LIQUID IRON-RIO

Palatable and easily assimilated. Does not produce Nausea, nor irritate the Stomach. Does not Cause Headache, nor Constipate. Does not Stain the Teeth. It is so Acceptable to the Stomach that its Use is Admissible when all other forms of Iron would be rejected. Being so Readily Assimilable, it only requires a small Dose.

Each Fluid Drachm contains ONE GRAIN of Iron in a Pleasant and Digestible Form.

DOSE.—One or more Teaspoonfuls as indicated, during or after meals.

S. H. KENNEDY'S

CONCENTRATED EXTRACT OF

PINUS CANADENSIS

DARK. A NON-ALCOHOLIC LIQUID. WHITE.

A MOST VALUABLE NON-IRRITATING MUCOUS ASTRINGENT.

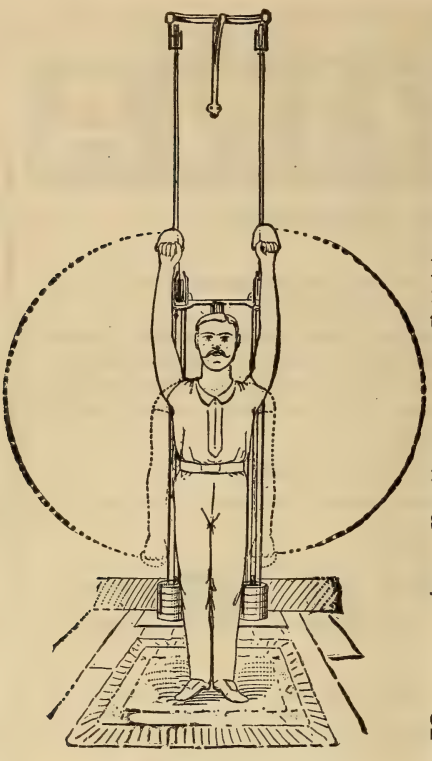
INDICATIONS.—Albuminuria, Diarrhea, Dysentery, Night-Sweats, Hemorrhages, Profuse Expectoration, Catarrh, Sore Throat, Leucorrhea, and other Vaginal Diseases, Piles, Sores, Ulcers, Burns, Scalds, Gonorrhea, Gleet, Etc.

When Used as an Injection, to Avoid Staining of Linen, the WHITE Pinus should be used.

RECOMMENDED BY PROMINENT EUROPEAN AND AMERICAN PHYSICIANS.

RIO CHEMICAL CO., St. Louis, Mo., U. S. A.

LONDON. PARIS. CALCUTTA. MONTREAL.



THE **Medical Profession** are cordially invited to visit our **GYMNASIUM SHOW-ROOM** containing over **FIVE THOUSAND DOLLARS** worth of apparatus for the **advancement of physical culture.**

Our O. K. Machine No. 2

Price, $10. Sent by Express to any part of the United States or Canada. No charge for casing.

Is endorsed by all **Physicians** who **have seen** it. It will develop any and every **muscle** of the body.

ADAPTED TO OLD AND YOUNG, MALE AND FEMALE.

We will mail our **Manual of Physical Culture,** together with **complete catalogue, free,** on application.

SPECIAL DISCOUNT TO THE PROFESSION.

1022 Market Street,

PHILADELPHIA.

SPORTING AND ATHLETIC GOODS OF EVERY DESCRIPTION.

No Chemicals.

W. BAKER & Co.'s Breakfast Cocoa

Is Absolutely Pure, and it is Soluble.

To increase the solubility of the powdered cocoa, various expedients are employed, most of them being based upon the action of some alkali, potash, soda or even ammonia. Cocoa which has been prepared by one of these chemical processes, can usually be recognized at once by the distinct alkaline reaction of the infusion in water.

W. Baker & Co.'s Breakfast Cocoa

is manufactured from the first stage to the last by perfect mechanical processes, **no chemical being used in its preparation.** By one of the most ingenious of these mechanical processes the greatest degree of fineness is secured without the sacrifice of the attractive and beautiful red color which is characteristic of an absolutely pure and natural cocoa.

BOUDAULT'S PEPSINE

The only Pepsine used in the Hospitals of Paris for the last Thirty Years.

Unlike the various substitutes which, in most cases, are but unscientific or incompatible compounds, forced upon the Medical Profession as aids to digestion by extensive advertising, but which, when submitted to the proper tests, are found to be useless as digestive agents, Pepsine is constantly gaining in the esteem of the careful practitioner.

Since the introduction of Pepsine by Boudault and Corvisart in 1854, the original BOUDAULT'S PEPSINE HAS BEEN AT ALL TIMES CONSIDERED THE BEST, as is attested by the awards it has received at the Expositions of 1867, 1868, 187 1873, in 1876 at the Centennial Exposition of Philadelphia, and in 1878 at the Paris Exposition.

The most reliable tests, carefully applied, will satisfy everyone that BOUDAULT'S PEPSINE HAS A MUCH HIGHER DIGESTIVE POWER than the best Pepsines now before the Profession, and is therefore especially worthy of their attention.

BOUDAULT'S PEPSINE is prepared in the form of Pepsine Acid and Pepsine Neutral. It is sold in bottles of one ounce, with a measure containing exactly five grains; also in bottles of four, eight, and sixteen ounces for dispensing.

BOUDAULT'S WINE OF PEPSINE

FORMULA OF DR. CORVISART.

The taste of Pepsine being perfectly disguised in this Wine, it may be recommended to persons who have difficulty in taking Pepsine in the form of Powder. This Wine is tested so that a tablespoonful of it is equal in digestive power to ten grains of Boudault's Pepsine in powder. Sold only in bottles of eight ounces.

TANRET'S PELLETIERINE

For the Treatment of Tape-Worm (Tænia Solium).

This New Tænifuge, the Active Alkaloid of Pomegranate Bark, has of late come into extensive use in France for the treatment of Tape-Worm (Tænia Solium). The results of numerous experiments with it at the Marine Hospitals of Toulon, St. Mandrier, etc., and in the Hospitals of Paris, St. Antoine, La Charité, Necker Beaujon, etc., have all been most satisfactory. Doctor Dujardin Beaumetz, Member of the Academy of Medicine, and Professor Laboulbene, in their report to the Society of Therapeutics, have given it their unqualified approval, after the most searching experiments. This preparation is pleasant to administer, and, if certain preliminaries are observed, success will be insured.

Sold only in bottles containing one dose.

DUCRO'S ALIMENTARY ELIXIR

A Combination uniting the properties of Alcoholic Stimulants and Raw Meat.

This preparation, which has been used with great success in the hospitals of Paris since 1868, is adapted to the treatment of all diseases requiring administration, in a small volume, of a tonic able to stimulate and support the vital forces, as *Pulmonar Phthisis, Depression and Nervous Debility, Adynamia, Malarious Cachexia, etc.*

Prepared by EMILE DURIEZ & CO., Successors to DUCRO & CIE, Paris.

KIRKWOOD'S INHALER

This is the only complete, reliable, and effective inhaler in use, arranged for the direct application of Muriate of Ammonia and other remedial agents in the state of vapor to the diseased parts of the air-passages in the treatment of catarrh and diseases of the throat and lungs. No heat or warm liquids required in its use.

It is entirely different from the various frail, cheap instruments that have been introduced.

KIRKWOOD'S INHALER is accompanied by testimonials of the highest professional character, together with carefully prepared formulas for use.

RETAIL PRICE, COMPLETE, $2.50.

☞ A liberal discount allowed to the trade and profession. For descriptive pamphlet or other information address

E. FOUGERA & CO., 30 North William St., New York,

B. SACHS, M.D., Professor of Diseases of the Mind and Nervous System; Consulting Neurologist to the Montefiore Home for Chronic Invalids.

THOMAS R. POOLEY, M.D., Professor of Ophthalmology; Surgeon-in-Chief of the New Amsterdam Eye and Ear Hospital; Ophthalmic Surgeon to the Sheltering Arms; Consulting Ophthalmologist to the St. Bartholomew's Hospital.

L. EMMETT HOLT, M.D., Professor of Diseases of Children; Visiting Physician to the New York Infant Asylum; Consulting Physician to the Hospital for Ruptured and Crippled.

AUGUST SEIBERT, M.D., Professor of Diseases of Children; Physician to the Children's Department of the German Dispensary.

H. MARION SIMS, M.D., Professor of Gynæcology; Gynæcologist to St. Elizabeth Hospital and New York Infant Asylum.

WILLIAM F. FLUHRER, M.D., Professor of Genito-Urinary Surgery; Surgeon to Bellevue and St. Sinai Hospitals.

*Deceased.

THE NEW YORK POLYCLINIC is a School of Clinical Medicine and Surgery for *Practitioners only.* No didactic lectures are given. The classes are limited. The demonstrations are made at the Polyclinic School and Hospital, and in the various Hospitals in New York City with which the Faculty are connected.

Session of 1889-'90 opens Monday, September 16th, 1889. Physicians matriculating for the Winter Session will be admitted to the Clinics from July 1st to September 14th, without additional charge. For further information and for catalogue, address

JOHN A. WYETH, M.D.,
Secretary of the Faculty,
Or WILLIS O. DAVIS, Clerk,
214, 216 & 218 East 34th Street, New York City.

UNIVERSITY OF MARYLAND
SCHOOL OF MEDICINE.

Eighty-third Annual Announcement, 1889-90. The next regular session will begin October 1st, 1889. A full course of didactic lectures, with ample clinical and dissecting-room facilities.

FACULTY:

GEORGE W. MILTENBERGER, M.D.,
Professor of Obstetrics.
CHRISTOPHER JOHNSON, M.D.,
Emeritus Professor of Surgery.
SAMUEL C. CHEW, M.D.,
Professor of Principles and Practice of Medicine and Hygiene.
FRANK DONALDSON, M.D.,
Emeritus Clinical Professor of Diseases of the Throat and Chest.
WILLIAM T. HOWARD, M.D.,
Professor of Diseases of Women and Children and Clinical Medicine.
JULIAN J. CHISOLM, M.D.,
Professor of Eye and Ear Diseases.
FRANCIS T. MILES, M.D.,
Professor of Physiology and Clinical Professor of Diseases of Nervous System.

L. McLANE TIFFANY, M.D.,
Professor of Surgery.
J. EDWIN MICHAEL, M.D.,
Professor of Anatomy and Clinical Surgery.
I. EDMONSON ATKINSON, M.D.,
Professor of Materia Medica and Therapeutics, Clinical Medicine and Dermatology.
R. DORSEY COALE, PH.D.,
Professor of Chemistry and Toxicology.
JOHN NOLAND MACKENZIE, M.D.,
Clinical Professor of Diseases of the Throat and Nose.
HERBERT HARLAN, M.D.,
Demonstrator of Anatomy.

For catalogue and further information, address: **Dr. J. EDWIN MICHAEL, Dean, 937 Madison Avenue.**

DENTAL DEPARTMENT.

Eighth Annual Announcement. Next regular session begins October 1st, 1889. New and excellent Infirmary and Laboratory, with abundance of clinical material.

FACULTY:

FRED. J. S. GORGAS, M.D., D.D.S.,
Professor of Principles of Dental Science, Dental Surgery, and Dental Mechanism.
JAMES H. HARRIS, M.D., D.D.S.,
Professor of Operative and Clinical Dentistry.
I. EDMONSON ATKINSON, M.D.,
Professor of Materia Medica and Therapeutics.
FRANCIS T. MILES, M.D.,
Professor of Physiology.
L. McLANE TIFFANY, M.D.,
Clinical Professor of Oral Surgery.

J. EDWIN MICHAEL, M.D.,
Professor of Anatomy.
R. DORSEY COALE, PH.D.,
Professor of Chemistry.
JOHN C. UHLER, M.D., D.D.S.,
Demonstrator of Mechanical Dentistry.
CHAS. L. STEEL, M.D., D.D.S.,
Demonstrator of Operative Dentistry.
HERBERT HARLAN, M.D.,
Demonstrator of Anatomy.
AND EIGHT ASSISTANT DEMONSTRATORS.

For catalogue and other information, apply to **Dr. F. J. S. GORGAS, Dean, 845 Eutaw Street, Baltimore.**

Medico-Chirurgical College of Philadelphia.

JAS. E. GARRETSON, A.M., M.D., Professor of Oral and Clinical Surgery.

WM. H. PANCOAST, A.M., M.D., Professor of General, Descriptive, and Surgical Anatomy and Clinical Surgery.

GEO. E. STUBBS, A.M., M.D., Professor of Clinical Surgery.

WM. F. WAUGH, A.M., M.D., Professor of Principles and Practice of Medicine and of Clinical Medicine.

ABRAHAM S. GERHARD, A.M., M.D., Professor of Forensic and Clinical Medicine.

WM. S. STEWART, A.M., M.D., Professor of Obstetrics and Clinical Gynecology.

H. EARNEST GOODMAN, M.D., Professor of Principles and Practice of Surgery and Clinical Surgery.

P. D. KEYSER, A.M., M.D., Dean, Professor of Ophthalmology.

SAMUEL B. HOWELL, A.M., M.D., Professor of Chemistry.

JOHN V. SHOEMAKER, A.M., M.D., Professor of Materia Medica, Pharmacology, Therapeutics and Clinical Medicine.

E. E. MONTGOMERY, B.S., M.D., Professor of Gynecology.

JAS. M. ANDERS, Ph.D., M.D., Professor of Hygiene and Clinical Diseases of Children; Associate Professor of Physiology

JOHN V. SHOEMAKER, A.M., M.D., Clinical Professor Skin Diseases.

FRANK WOODBURY, A.M., M.D., Honorary Professor of Clinical Medicine.

WM. B. ATKINSON, A.M., M D. Honorary Professor of Sanitary Science and Paediatrics.

The Regular Session begins September 30th, 1889, and continues until the middle of April. It is preceded by a Preliminary Session of three weeks, and followed by a Spring Session lasting until the middle of June.

Seats are issued in the order of matriculation, and are forfeitable if fees are not paid before November 1st.

Preliminary examination or equivalent degree, and a three years' graded course obligatory. A fourth year voluntary.

Instruction is given by lectures, clinical teaching and practical demonstrations. In the subjects of Anatomy, Pharmacy, Chemistry, Histology and Pathology the usual methods of instruction are largely supplemented by laboratory work.

Examinations are held at the close of each Regular Session upon the studies of the term. Although the degree of Doctor of Medicine is conferred at the end of the third year, a fourth year is earnestly recommended, at the end of which the degree of Doctor of Medicine *cum laude* is given.

FEES.

Matriculation, $5; first and second years, each, $100; third year (no graduation fee), $100; fourth year, free to those who have attended three sessions in this school, to all others, $100.

Extra charges only for material used in the laboratories and dissecting-room.

For further information or announcement, address,

E. E. MONTGOMERY, M.D., Secretary,
Medico-Chirurgical College,
Cherry, below 18th Street, Philadelphia, Penna.

Medical College of Ohio.

Medical Department of the University of Cincinnati.

The Seventy-first Annual Session will begin September 4, 1889, and continue until March 1, 1890.

FEES.—Matriculation Ticket, $5.00; General Lecture Ticket, $75.00; Hospital Ticket, $5.00; Graduation Fee, $25.00.

For circulars, and further information, address

JAMES G. HYNDMAN, M.D., Secretary,
22 West Ninth Street, Cincinnati, Ohio.

WESTERN PENNSYLVANIA MEDICAL COLLEGE

CITY OF PITTSBURGH.

SESSIONS OF 1889—90.

The REGULAR SESSION begins on the last Tuesday of September, and continues six months. During this session, in addition to four Didactic Lectures, two or three hours are daily allotted to Clinical Instruction. Attendance upon two regular courses of lectures is requisite for graduation. A three years' graded course is also provided. The SPRING SESSION embraces recitations, clinical lectures and exercises, and didactic lectures on special subjects; this session begins the second Tuesday in April, and continues ten weeks.

The laboratories are open during the collegiate year for instruction in chemistry, microscopy, practical demonstrations in medical and surgical pathology, and lessons in normal histology. Special importance attaches to "the superior clinical advantages possessed by this College." For particulars, see annual announcement and catalogue, for which, address the Secretary of Faculty, Prof. J. W. J. McKENNAN.

Business correspondence should be addressed to
PROF. W. J. ASDALE, 2107 Penn Avenue, Pittsburgh.

Woman's Medical College

OF BALTIMORE.

S. E. Cor. Druid Hill Ave. and Hoffman St., Baltimore, Md.

THE EIGHTH ANNUAL SESSION WILL BEGIN ON WEDNESDAY, OCTOBER 2d, 1889.

For further information or catalogue, address
RANDOLPH WINSLOW, M.D., Acting Dean,
No. 1, Mount Royal Terrace, Baltimore, Md.

Medical Department, State University of Iowa, at Iowa City, Iowa.

The next Session will begin on September 11, 1889, and continue until March 12, 1890. Attendance upon three courses of lectures, of six months each, is requisite to graduation. The facilities for dissection and clinical study are unsurpassed.

TERM EXPENSES—Lecture Ticket, $20.00; Demonstrator's Ticket, $10.00; Matriculation Ticket, $5.00 (paid but once); Hospital Ticket, $3.00; Examination Fee (for final examination) $25.00. No charge for dissecting material. For further information, address DR. A. C. PETERS, Ast. Sec'y, Iowa City, Iowa.

THE

College of Physicians and Surgeons

OF CHICAGO.

Regular Session opens Sept. 23, 1889.

GRADED COURSE OF INSTRUCTION.

Excellent Clinical Advantages.

The College Building (directly opposite Cook County Hospital) is one of the most complete and elaborate edifices devoted to medical teaching in this country.

FEES.—WINTER SESSION.—Matriculation (paid annually), $5.00. General Ticket, admitting to all the lectures, and including all practical work in the chemical and physiological laboratories, $60.00. For further information or announcements, address

PROF. W. E. QUINE, Secretary,
Or 3160 Indiana Avenue.
PROF. A. REEVES JACKSON, President,
271 Michigan Avenue, Chicago, Illinois.

DETROIT COLLEGE OF MEDICINE.

SESSION 1889-90.

Clinical and Practical teaching are made an important feature of this College. Clinical instruction is given daily at HARPER, ST. MARY'S and ST. LUKE'S HOSPITAL, at the COLLEGE, at COLLEGE EYE and EAR INFIRMARY, ST. MARY'S FREE EYE and EAR INFIRMARY, and at the three FREE DISPENSARIES. The facilities offered by this college are unsurpassed for the practical study of MEDICINE, SURGERY, OBSTETRICS, GYNÆCOLOGY, DISEASES OF CHILDREN, GENITO-URINARY, and ORTHOPÆDIC SURGERY, OPHTHALMOLOGY and OTOLOGY, DERMATOLOGY and LARYNGOLOGY.

REGULAR SESSION opens on Wednesday, Sept. 25, and continues six months. During the session, the Professors will take special pains to examine the Students upon the subjects of the previous lectures.

SPRING SESSION begins April 2d, 1890; and closes June 11th.

FEES.—Matriculation fee, $5; Fees for Regular Session, $50; Spring Session, $10, to those who attend the regular term—to all others, $25; Hospital Fee, $10; Graduation Fee, $30; Perpetual Ticket, $100.

For further particulars, and for College Circular, apply to

H. O. WALKER, M.D., Secretary,
33 Lafayette Ave., Detroit, Mich.

UNIVERSITY OF PENNSYLVANIA.—Medical Department.

The 124TH ANNUAL WINTER SESSION will begin Tuesday, October 1st, 1889, at 12 M., and continue until May 1st, 1890.

The PRELIMINARY SESSION begins September 18th, 1889.

The curriculum is graded and three annual winter sessions are required. Practical instruction, including laboratory work in Chemistry, Histology, Osteology and Pathology, with Bedside Instruction in Medicine, Surgery and Gynecology are a part of the regular course and without additional expense.

FACULTY.

JOSEPH LEIDY, M.D., LL.D., Professor of Anatomy.
D. HAYES AGNEW, M.D., LL.D., Honorary Professor of Clinical Surgery.
WILLIAM PEPPER, M.D., LL.D., Professor of Theory and Practice of Medicine, and of Clinical Medicine.

COLDEN'S LIQUID BEEF TONIC

AN INVALUABLE AID IN MEDICAL PRACTICE.

ORIGINAL | COLDEN'S LIEBIG'S LIQUID EXTRACT OF BEEF AND TONIC INVIGORATOR. | LABEL.

ESSENTIALLY DIFFERENT FROM ALL OTHER BEEF TONICS. UNIVERSALLY ENDORSED BY LEADING PHYSICIANS.

This preparation, consisting of the Extract of Beef (prepared by Baron Liebig's process), the best Brandy obtainable, soluble Citrate of Iron, Cinchona and Gentian is offered to the Medical Profession upon its own merits. It is of inestimable value in the treatment of **Debility, Convalescence from Severe Illness Anæmia, Malarial Fever, Chlorosis, Incipient Consumption, Nervous Weakness,** and maladies requiring a Tonic and Nutrient. It is quickly absorbed by the Stomach and upper portion of the Alimentary Canal, and therefore finds its way into the circulation quite rapidly.

COLDEN'S LIQUID BEEF TONIC appeals to the judgment of intelligent Physicians in the treatment of

ALL CASES OF GENERAL DEBILITY.

By the urgent request of several eminent members of the medical profession, I have added to each wineglassful of this preparation two grains of Soluble Citrate of Iron, and which is designated on the label, **"With Iron, No. 1;"** while the same preparation, **Without Iron,** is designated on the label as **"No. 2."**

In prescribing this preparation, physicians should be particular to mention *"COLDEN'S,"* viz., *"Ext. Carnis Fl. Comp. (Colden)."* A Sample of **COLDEN'S BEEF TONIC** will be sent free on application, to any physician (enclosing business card) in the United States. *Sold by druggists generally.*

C. N. CRITTENTON, General Agent, 115 Fulton St., New York.

GLENN'S SULPHUR SOAP.

BEWARE OF COUNTERFEITS.

Physicians know the great value of the local use of Sulphur in the **Treatment of Diseases of the Skin.**

Constantine's Pine-Tar Soap.

THE BEST SOAP MADE.

Has been on trial among physicians for very many years as a healing agent. **By far the Best Tar Soap made.**

Wholesale Depot, C. N. CRITTENTON, 115 Fulton St., New York.

Samples of above Soaps SENT FREE, on application, to any Physician enclosing card.

FELLOWS'

HYPO-PHOS-PHITES

(SYR: HYPOPHOS: COMP: FELLOWS)

Contains **The essential elements** to the Animal Organization—Potash and Lime.

The **Oxydizing Agents**—Iron and Manganese;

The **Tonics**—Quinine and Strychnine,

And the **Vitalizing Constituent**—Phosphorus,

Combined in the form of a Syrup, with *slight alkaline reaction.*

It Differs in Effect from all others, being pleasant to taste, acceptable to the stomach, and harmless under prolonged use.

It has Sustained a High Reputation in America and England for efficiency in the treatment of Pulmonary Tuberculosis, Chronic Bronchitis, and other affections of the respiratory organs, and is employed also in various nervous and debilitating diseases with success.

Its Curative Properties are largely attributable to Stimulant, Tonic, and Nutritive qualities, whereby the various organic functions are recruited.

In Cases where innervating constitutional treatment is applied, and tonic treatment is desirable, this preparation will be found to act with safety and satisfaction.

Its Action is Prompt; stimulating the appetite and the digestion, it promotes assimilation, and enters directly into the circulation with the food products.

The Prescribed Dose produces a feeling of buoyancy, removing depression or melancholy, and hence is of great value in the treatment of MENTAL AND NERVOUS AFFECTIONS.

From its exerting a double tonic effect and influencing a healthy flow of the secretions, its use is indicated in a wide range of diseases.

Prepared by JAMES I. FELLOWS, Chemist,

ACCIDENTS AND EMERGENCIES

By CHARLES W. DULLES, M.D.

"A work that ought to be in every home, and every home that has a copy kept where it can be consulted at short notice is likely to find it worth many times its small cost."—*Philadelphia Evening Telegraph*, May 5, 1888.

"The methods of treatment recommended are trustworthy and reliable. The manual is one of the best of this class of books and should be in the library of every householder, ready for reference at a moment's notice."—*Science*, May 18, 1888.

Sent on receipt of 75 Cents.

ADDRESS:

Publisher Medical and Surgical Reporter,

P.O. Box 843. PHILADELPHIA, PA.

The utility of artificial legs and arms with rubber feet and hands is evidenced by the operations of over nine thousand men, women, and children distributed throughout the entire civilized world. Strange as it may seem, this army mingles with the vast populace and their misfortunes are lost to sight. Men engaged in all manner of vocations, manual, arduous, menial, on the farm, at the forge, in the mines, at the desk. Women attend to their household duties, whether in the kitchen, laundry, drawing-room, or parlor. Children wearing one or a pair of artificial limbs are no longer objects of pity and dependence; they indulge with other children in all manner of sports, they skate, ride the bicycle, romp and tumble about just as healthy and merry children should do.

One little fellow from Connecticut writes: "I can climb trees, play base-ball, and other out-door games as well as other 14-year-old boys."

A large illustrated book, containing 400 pages and over 200 illustrations, will be sent free to those needing artificial legs and arms, or to physicians and others interested.

This book gives instructions how to order and be fitted while the subject remains at home.

A. A. MARKS, 701 Broadway, New York City.

ESTABLISHED OVER 36 YEARS.

McARTHUR'S SYRUP.

(SYR: HYPOPHOS: COMP: C. P. McARTHUR.)

Its use is indicated in Consumption and Tuberculosis, Diseases of the Chest, Chronic Cough, Throat Affections, General Debility, Brain Exhaustion, Impotence and Loss of Memory.

The point of primary importance in the use of the Hypophosphites is their *chemical* purity, but unfortunately they are too often adulterated.

So little seems to be generally known, even among the medical profession, with regard to the chemistry of the Hypophosphites, and the absolute necessity of CHEMICAL purity, that we call attention to this point.

One of the first effects produced by the use of our CHEMICALLY PURE Hypophosphites is a general increase of nervous energy, with a feeling of ease and comfort.

The second effect is an increase of appetite; digestion is improved, and the bowels become regular in their action, the quantity and color of the blood is increased, respiration is controlled, a better expansion of the chest is observed, cough improves, easy expectoration is produced, night perspiration diminishes, the face becomes fuller, the lips red, the nails and hair grow, and in children the teeth, showing the importance of the Hypophosphites on the organ of nutrition.

☞ Physicians when prescribing will please write thus:

℞ SYR: HYPOPHOS: COMP: McARTHUR. ONE BOTTLE.

As it is made *only for physicians* there are no printed wrappers or advertisements about the bottle.

Our pamphlet on the **CURABILITY AND TREATMENT OF CONSUMPTION,** sent free to physicians upon application.

We will send one bottle of McArthur's Syrup to any physician, without charge, who will pay the express charges on the same.

Mention this Journal. McARTHUR HYPOPHOSPHITE CO., BOSTON, MASS.

THE NEW HYPNOTIC
SULFONAL-BAYER.

SULFONAL was discovered by Prof. Eugen A. Baumann, of Freiburg University, and was first prepared by the Farbenfabriken vorm. Friedr. Bayer & Co., Elberfeld.

SULFONAL (Diæthylsulfondimethylmethan) is in the form of colorless prisms, odorless, and tasteless, melting at 125.5° C. (258° F.) and has the composition $(C H_3)_2=C=(C_2 H_5 SO_2)_2$. It is slightly soluble in cold water, but easily soluble in hot water or alcohol.

SULFONAL was first examined as to its physiological and pathological effects by Prof. A. Kast, of Freiburg University, and its hypnotic action was discovered and studied by him.

Since then SULFONAL has been the subject of numerous trials and experiments by many eminent and experienced physicians. Their testimony is unanimously favorable, and the conclusions reached by them are as follows:

SULFONAL is a prompt and reliable hypnotic, which in proper doses, produces quiet, natural sleep, lasting a number of hours.

SULFONAL has no unfavorable effects on the heart and the circulation, nor on the temperature, the pulse, or the respiration.

SULFONAL produces no disagreeable secondary symptoms; the patients with very few exceptions awake from their sleep feeling strong and greatly refreshed.

SULFONAL does not interfere with the process of digestion.

SULFONAL is a hypnotic, and not a narcotic; it acts by giving rest to the cells of the cerebral cortex, thereby causing sleep.

SULFONAL does not create an unconquerable desire for its repeated use; there is no danger of a SULFONAL-habit. Neither is it necessary to increase the dose after long-continued use.

SULFONAL is best administered at supper-time, dissolved in hot liquids, *e. g.*, a bowl of soup or broth, a cup of milk, tea, coffee, cocoa, etc.

These points will be found to be fully exhibited in the series of contributions contained in our pamphlet, which will be mailed on application.

SULFONAL-BAYER is supplied by us in half-ounce and one-ounce vials.

We prepare 5-grain and 15-grain Tablets of Sulfonal-Bayer. The tablet form is admirably adapted to the purpose of administering this drug, as when they are placed in the liquids, they disintegrate and are thus received into the system.

We also put up Sulfonal-Bayer in the form of our Soluble Pills, containing five grains each.

THE NEW ANTIPYRETIC
PHENACETINE-BAYER.

Phenacetine-Bayer (Para-Acetphenetidine) is a white, glossy, crystalline powder, perfectly tasteless, melting at 135° C.=307° F and has the composition $C_6 H_4 <^{O.C_2H_5}_{NH(CO-CH_3)}$.

It is slightly soluble in water, a little more soluble in glycerine, but most freely in alcohol.

Phenacetine-Bayer was first prepared by the Farbenfabriken, formerly Friedr. Bayer & Co., Elberfeld, and is of absolute purity and uniform quality.

Summarizing the superiority of Phenacetine-Bayer over other antipyretics and antineuralgics, the following conclusions are formed:

1. ***Phenacetine-Bayer is an efficacious antipyretic.***
2. ***It does not develop any disagreeable or noxious after-effects.***
3. ***The dose required is half that of Antipyrine.***
4. ***It is perfectly tasteless.***
5. ***On account of its innocuousness and tastelessness, it is a valuable antipyretic both in adults and in children.***
6. ***Phenacetine-Bayer is an important antineuralgic; its effect is more energetic than that of Antipyrine and does not cause lassitude or any other disagreeble symptoms.***

Our pamphlet on Phenacetine-Bayer, containing the valuable testimony of eminent physicians will be mailed on application.

We offer Phenacetine-Bayer in one-ounce vials, or in the form of our Soluble Pills of the strength of two and four grains to each pill.

W. H. SCHIEFFELIN & CO.,

170 & 172 WILLIAMS STREET, NEW YORK,

SOLE LICENSEES AND SOLE AGENTS FOR THE UNITED STATES

SUCCUS ALTERANS

(McDADE.)

SUCCUS ALTERANS is a purely vegetable compound of the preserved juices of Stillingia Sylvatica Lappa Minor, Phytolacca Decandra, Smilax Sarsaparilla, and Xanthoxylum Carolinianum, as collected by DR. GEO. W. MCDADE, exclusively for ELI LILLY & Co., and endorsed by DR. J. MARION SIMS.

SUCCUS ALTERANS continues to gain favor from its remarkable Alterative and Tonic properties, *eliminating specific poison from the blood* and *increasing the proportion of red corpuscles in anæmic patients* to a wonderful degree; is endorsed by the medical profession, and in use by many hospitals of note.

SUCCUS ALTERANS in venereal and cutaneous diseases is fast supplanting Mercury, the Iodides, and Arsenic; and is a certain remedy for Mercurialization, Iodism, and the dreadful effects often following the use of Arsenic in skin diseases.

SUCCUS ALTERANS is also strongly recommended for its Tonic and Alterative effects in myriad forms of scrofulous disease, and in all cases where anæmia is a factor. Such patients rapidly develop a good appetite, sleep soundly, and gain flesh rapidly. Many cases are on record where patients increased ten to twenty-five pounds in weight in a few weeks.

SUCCUS ALTERANS is giving satisfactory results in treatment of *Chronic Rheumatism*, and can be used with confidence.

SUCCUS ALTERANS may be given for any length of time, without injury to the patient.

SUCCUS ALTERANS is put up in pint round amber bottles, and *never in bulk.*

PHYSICIANS who have not received DR. MCDADE'S latest publication, the MONOGRAPHIA SYPHILITICA, should send their address, mentioning this journal, and we will mail a copy. It contains a paper, illustrated with colored plates, by DR. D. H. GOODWILLIE, of New York, on the "Sequelæ of Syphilis," reports of cases in practice, and many other valuable papers.

ELIXIR PURGANS.

ELIXIR PURGANS (LILLY) reliably stimulates the dormant liver without undue irritation, and has gentle yet positive effect upon the alimentary tract. In HABITUAL CONSTIPATION, so common in WOMEN AND CHILDREN, it will be found particularly useful. Its endorsement at Bellevue and many other prominent hospitals East and West, as well as its employment in general practice by the most eminent medical men, confirms the experience of years in its use.

Each Teaspoonful Represents	
Rhamnus Purshiana, -	**10 grs.**
Euonymus Atropur., - -	**8 grs.**
Cassia Acutifolia (Purif.)	**10 grs.**
Iris Versicolor, - - -	**4 grs.**
Hyoscyamus Niger, -	**2 grs.**
Aromatics, etc.	

IN PRESCRIBING, PLEASE BE CAREFUL TO WRITE

ELIXIR PURGANS (LILLY),

THAT OTHER PREPARATIONS MAY NOT BE SUBSTITUTED.

HIGHLY RECOMMENDED.

We take pleasure in endorsing the ELIXIR PURGANS (LILLY) as prepared from the above formula for in it we find a near approach to positive *perfection* in the form of a *Liquid Cathartic*, and, from our experience with the preparation, can highly recommend it to the profession.

"Aconitine produces marvelous effects in the treatment "of *facial neuralgias* when they are not symptomatic of "intracranial tumor."—*Society of Biology of Paris, Meeting* "*of the 28th February, 1880.*

Dose—Take 3 to 6 pills during the twenty-four hours.

ACCEPT ONLY THE GENUINE MOUSSETTE PILLS OF

CLIN & CO.,—Paris.

GRAND NATIONAL PRIZE OF 16,600 FRANCS,

QUINA-LAROCHE

This meritorious **Elixir, QUINA-LAROCHE,** is prepared from the **three** Cinchonas; it is an agreeable and doubtless highly efficacious remedy.

—*The Lancet.*

VINOUS ELIXIR,

A STIMULATING RESTORATIVE

—AND—

ANTI-FEBRILE TONIC.

QUINA-LAROCHE under the form of a vinous **Elixir** contains the totality of the numerous principles of the **three** Cinchona barks. It is a preparation which renders great services to Therapeutics.—Extract of the *Gazette des Hôpitaux*, Paris.

FAR SUPERIOR TO ALL ORDINARY CINCHONA WINES.

LAROCHE'S QUINA, tried by the Academy of Medicine of Paris, is a specially prepared COMPOUND EXTRACT of Quinquina, a careful analysis, confirmed by experience, has shown that most of the wines and syrups hitherto used have not contained all the properties of this precious bark, of these some, although beneficial, are altogether lost, while many preparations contain but half the properties of the bark in varying proportions.

MR. LAROCHE, by his peculiar method, has succeeded in extracting all the active principles of the quinquina, combining these with *Catalan Wine* forming an Elixir free from the disagreeable bitterness of other similar preparations. Practitioners have found triple advantages in the use of this Elixir, it is a *strong tonic*, is easily administered, and perfectly harmless, being free from the unpleasant effects of Quinine.

THE FERRUGINOUS QUINA-LAROCHE is the invigorating tonic *par excellence*, having the advantage of being easily assimilated by the gastric juice; without, in any way, deranging the action of the digestive organs, proving itself to be a most efficacious remedy in cases of impoverishment of the blood, ANÆMIA, CHLOROSIS, INTESTINAL HÆMORRHAGE, CASTRALGIA, EXHAUSTION, ETC., ETC.

GENUINE BLAUD'S PILLS.

These pills, which have been inserted in the new French Pharmacopœia, have been employed with the greatest success for more than fifty years by most French and foreign physicians, to cure anemia, chlorosis, and all chlorotic affections in which iron is indicated.

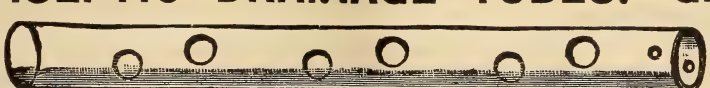
Here is the opinion of men most eminent in medical science who have employed them:

"For thirty-five years, in which I have practised medicine, I have recognized the incontestable advantages of BLAUD'S PILLS over all other ferruginous preparations, and I regard them as the best anti-chlorotic."—DR. DOUBLE, *Ex-President of the Academy of Medicine.*

"Of all the ferruginous preparations, which have given good results in the treatment of chlorotic affections, BLAUD'S PILLS appear to us to deserve to hold the first rank."—*Dictionnaire universel de médecine*, Vol. II, p. 99.

These pills, prepared according to the genuine formule of the originator, by his nephew, Aug. Blaud, Pharmacist of the Faculty of Paris, are sold only in bottles of 200 pills and half bottles of 100 pills, at a cost of 5 and 3 francs ($1.00, and seventy-five cents), and never in smaller quantities. *See that his name is stamped on each pill.* **PARIS, 8 RUE PAYENNE, and at every Pharmacy.** (Beware of imitations.)

ANTISEPTIC DRAINAGE TUBES.—Glass.



These Tubes have large holes, one-half inch apart, arranged alternately on opposite sides.

They are carefully finished, especial care being taken to make them smooth.

In addition to the drainage-holes, each tube has at one end two smaller holes for the insertion of Safety-Pin, through which it is prevented slipping into the wound.

FURNISHED IN SEVEN SIZES.

BROMIDIA

THE HYPNOTIC.

FORMULA.—

Every fluid drachm contains 15 grains EACH of Pure Chloral Hydrat. and purified Brom. Pot., and one-eighth grain EACH of gen. imp. ext. Cannabis Ind. and Hyoscyam.

DOSE.—

One-half to one fluid drachm in WATER or SYRUP every hour, until sleep is produced.

INDICATIONS.—

Sleeplessness, Nervousness, Neuralgia, Headache, Convulsions, Colic, Mania, Epilepsy, Irritability, etc. In the restlessness and delirium of fevers it is absolutely invaluable.

IT DOES NOT LOCK UP THE SECRETIONS.

PAPINE

THE ANODYNE.

Papine is the Anodyne or pain-relieving principle of Opium, the Narcotic and Convulsive Elements being eliminated. It has less tendency to cause Nausea, Vomiting, Constipation, Etc.

INDICATIONS.—

Same as Opium or Morphia.

DOSE.—

(ONE FLUID DRACHM)—represents the Anodyne principle of one-eighth grain of Morphia.

IODIA

The Alterative and Uterine Tonic.

FORMULA.—

Iodia is a combination of active principles obtained from the Green Roots of Stillingia, Helonias, Saxifraga, Menispermum, and Aromatics. Each fluid drachm also contains five grains Iod. Potas., and three grains Phos. Iron.

DOSE.—

One or two fluid drachms (more or less as indicated) three times a day before meals.

INDICATIONS.—

Syphilitic, Scrofulous and Cutaneous Diseases, Dysmenorrhea, Menorrhagia, Leucorrhea, Amenorrhea, Impaired Vitality, Habitual Abortions, and General Uterine Debility.

THE SUSTAINED SUPREMACY

OF

Fairchild's Pepsin,

In ACTIVITY, PERMANENCE and GENERAL EXCELLENCE

Has won for this product a wide use and recognition in all the principal markets of the world.

We guarantee it to be unchangeable, to maintain its activity and quality under all ordinary commercial conditions; it is therefore, by far the most available for the dispensing counter, as well as in the manufacture of every form of pepsin preparation.

Under exactly parallel conditions, with any proper percentage of acidity and with any proportion of such acidulated water to the albumen, Fairchild's pepsin is positively superior to any pepsin known.

It will, under absolutely comparative conditions, grain for grain, digest more albumen than any other pepsin made.

We will be pleased to send samples to any physician who may wish to ascertain for himself the relative activity of Fairchild's pepsin, or to submit it to any practical trial.

Prices and complete information upon application.

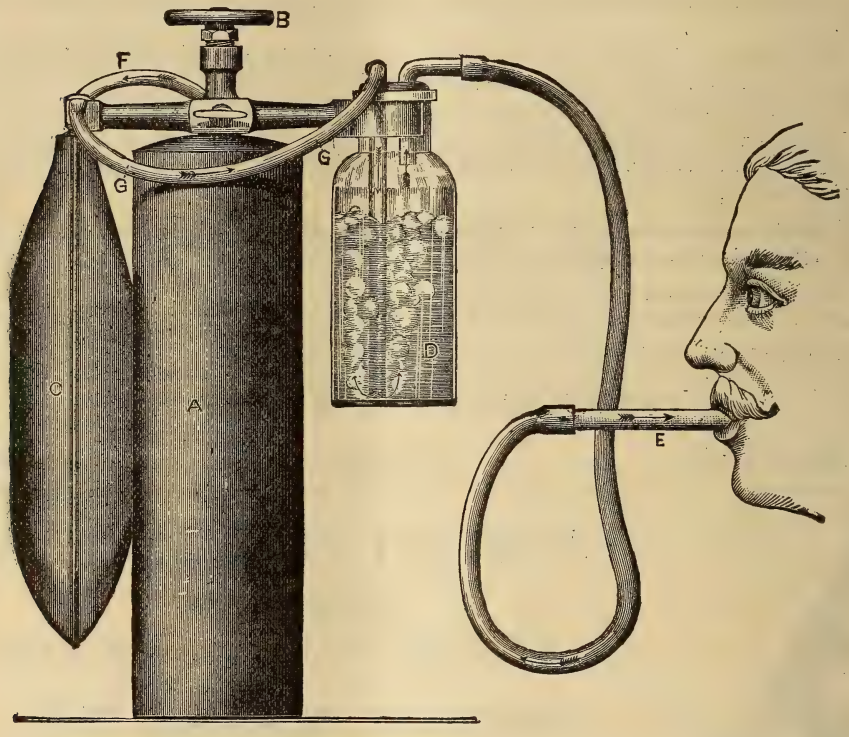
INHALATION APPARATUS

FOR

THE THERAPEUTIC ADMINISTRATION OF OXYGEN.



In the treatment of lung troubles by Oxygen its exhibition by inhalation is preferred. The apparatus herewith shown is a modification of the Nitrous Oxide apparatus which we have supplied for many years. It is made in the best manner throughout, and is the outcome of years of experience in the manufacture of gas apparatus. It will be found to meet all the requirements.

We supply the gas in two sizes of cylinders, containing respectively forty and one hundred gallons, either pure Oxygen, or a mixture of Oxygen and Nitrous Oxide in definite proportions of 20 per cent., and forty per cent. of Nitrous Oxide.

Whether pure or mixed the gas is sold at the uniform price of 5 cents a gallon. The cost of the cylinders will be refunded on their return empty with the valves in good condition. Full description of Inhalation and Enema apparatuses with directions for use accompany each apparatus, or will be supplied on application.

PRICES.

Inhalation Apparatus	$5.00
Cylinder, 40 gallons' capacity	6.00
40 gallons Gas, either pure Oxygen or mixed Oxygen and Nitrous Oxide	2.00
Complete Apparatus, Cylinder, and 40 gallons Gas	$13.00
Inhalation Apparatus	$5.00
Cylinder, 100 gallons' capacity	15.00
100 gallons Gas, either pure or mixed	5.00
Complete Apparatus, Cylinder, and 100 gallons Gas	$25.00

LISTERINE

NON-TOXIC, NON-IRRITANT, NON-ESCHAROTIC.

FORMULA—Listerine is the essential antiseptic constituent of Thyme, Eucalyptus, Baptisia, Gaultheria and Mentha Arvensis, in combination. Each fluid drachm also contains two grains of refined and purified Benzo-boracic Acid.

DOSE—Internally: One teaspoonful three or more times a day (as indicated) either full strength, or diluted, as necessary for varied conditions.

LISTERINE is a well-proven antiseptic agent—an antizymotic—especially adapted to internal use, and to make and maintain surgical cleanliness—asepsis—in the treatment of all parts of the human body, whether by spray, irrigation, atomization, or simple local application, and therefore characterized by its particular adaptability to the field of

PREVENTIVE MEDICINE—INDIVIDUAL PROPHYLAXIS.

Diseases of the Uric Acid Diathesis.
LAMBERT'S
LITHIATED HYDRANGEA
KIDNEY ALTERATIVE—ANTI-LITHIC.

FORMULA—Each fluid drachm of "Lithiated Hydrangea" represents thirty grains of FRESH HYDRANGEA and three grains of CHEMICALLY PURE Benzo-Salicylate of Lithia. Prepared by our improved process of osmosis, it is INVARIABLY of DEFINITE and UNIFORM therapeutic strength, and hence can be depended upon in clinical practice.

DOSE—One or two teaspoonfuls four times a day (preferably between meals).

Urinary Calculus, Gout, Rheumatism, Bright's Disease, Diabetes, Cystitis, Hæmaturia Albuminuria, and Vesical irritations generally.

We have much valuable literature upon { GENERAL ANTISEPTIC TREATMENT, LITHEMIA, DIABETES, CYSTITIS, ETC. } To forward to Physicians upon request.

CALIFORNIA VINTAGE CO.
21 PARK PLACE N.Y.

Geo Hamlin Prest. Chas Roome Parmele Treas.

GENTLEMEN:

The Case of your wines sent me for analysis by Dr. A. L. Hummel, of the "Annals of Hygiene," containing specimens of your La Rosa Zinfandel, Mataro, Riesling, Royal Tokay, and Royal Grape Brandy, has been duly received.

I have examined them for the common contaminants of wine; to wit: Sulphurous acid and sulphites, salicylic acid, fuchsin, lead salts, etc., none of which I found present therein.

I have also determined their alcoholic strength, extractives, and ashes, and found them to correspond strictly in this respect with the standard of pure and natural wines, which cannot be said of many of the imported wines.

As a native of a wine-producing country, I consider myself somewhat of a judge of wines, and regard your products as comparing more than favorably with most of the wines from abroad which are sold at higher prices, so much so that I enclose within my order for fifty bottles of La Rosa Zinfandel, which I expect to use hereafter exclusively at my table.

Very Respectfully,

L. WOLFF, M.D.,
Demonstrator of Chemistry, Jefferson Medical College.

GREEN DRUG
FLUID EXTRACTS.

——CHARACTERISTICS.——

Uniform Strength, Convenience of administration,
Non-liability to deterioration by age,
Positive therapeutic efficacy.

The WM. S. MERRELL CHEMICAL CO. will not hold themselves responsible for the identity of Fluid Extracts, filled out by druggists from bulk stock, even though the written label may read "*Merrell's.*"

CAUTION—accept original packages only.

☞ *Read our Monograph—Green Drug Fluid Extracts—Their origin, history, and rationale.*

Sent free to any address.

PRICE REDUCED.

True Salicylic Acid.

CRYSTALLIZED FROM

WINTERGREEN OIL.—ITS NATURAL SOURCE.

DR. P. W. LATHAM, Downing Professor of Medicine at Cambridge (England), lecturing on the treatment of gout and rheumatism at the Royal College of Physicians, says:

"The true Salicylic Acid obtained from the vegetable kingdom must alone be employed. If you have to give large doses, avoid giving the artificial product obtained from carbolic acid, however much it may have been dialyzed and purified. Give the acid without any alkali or base," etc.

A reprint of this exceedingly valuable paper will be sent on application.

A DESIDERATUM—not always appreciated.

The quality of medicines used in the prescription is as important a factor in the cure of disease as a correct diagnosis; and a physician violates no code, either of ethics or morals, in demanding of his druggist that which he knows to be reliable, instead of leaving to the latter to decide whose preparations he shall or shall not use.

DIAMOND MARK.

And insist upon receiving the HUNGARIAN APERIENT WATER of the APOLLINARIS COMPANY, LIMITED, London.

THE VALUE OF NUTRITION IN DISEASE.

All physicians who have ever used Murdock's Liquid Food and Suppositories recognize their value over all other foods, in breaking up disease and building up the patients after disease, preventing a relapse, **as the same results are obtained as in surgery.** Its value in surgical cases we illustrate by the records of the different cities and of Murdock's Free Surgical Hospital for Women, which is the largest in the United States. It contains 114 beds, every bed free, including operation, the operations ranging from 1000 to 1200 yearly, representing 90 of the worst classes known in surgery. Among these cases we have had **Cancer of uterus** (*Kolpo-hysterectomy*), 13; **Salpingitis** (*Tait's operation*), 31; **Fibroid of uterus** (*abdominal hysterectomy*), 19; **Ventral operation, hernia,** (*abdominal section*), 12; **Cancer of bowel** (*incision*), 2; **Parovarian cyst, 6; Papillomatous cyst** (*extirpation*), 4; **Tubercular peritonitis** (*incision*), 1; **Ovarian cystoma 27; Nymphomania** (*Battey*), 1; **Exploratory abdominal incisions, 12; Fibroid with abdominal abscess** (*Hegar*), 2; **Hysterorraphy, 2; Dermoid cyst, 3; Cirrhotic ovaries,** (*Battey*), 4; **Fibroid uterus** (*Hegar*), 6; **Hystero-epilepsy** (*Battey*), 1; **Haemato-Salpinx** (*Tait*), 5; **Rupture of intestine into vagina, 1; Dislocated kidney, 2; Fibroid tumor abdominal wall, 1; Resection of intestine** (*Senn*), 1; **Ruptured perineum, 294.** Patients are in the Hospital 8 days before and 26 days after operation, on an average.

In Boston, last year, 42 deaths were from Cancer in the Breast. In Murdock's Hospital, 35 such cases were operated on without a death, the patients remaining in the Hospital, on an average, 18 days.

Mortality	in Boston,	25.60	per 1000.
"	of Women in Boston,	29,00	" "
"	in **Murdock's Free Surgical Hospital,**	**5.00**	" "
"	New York,	26.32	" "
"	Philadelphia,	20.00	" "
"	Chicago,	20.90	" "
"	St. Louis,	20.49	" "

showing our mortality is only one-sixth as great as of those in health. As good results were obtained in our General Hospital, which we kept open 27 months, **thus showing the value of nutrition as found in Murdock's Liquid Food, and so recognized by the British and American Medical Associations,** before which essays were read and discussed, and it is the only Raw food preparation on which essays were ever read.

Physicians are invited to visit our Hospitals and Works, also to send in patients and to be present at the operations. For any physician who has not used our Liquid Food (and Suppositories for adults and infants), we will deliver free samples to any express company in Boston.

When babies do not thrive, never change their food, but add five or more drops at each feeding of Murdock's Liquid Food, and their lost or needed vitality will be restored in less than thirty days. It is invaluable when weaning babies or when teething. If mothers will take one teaspoonful to a tablespoonful before each meal and on retiring, they will receive as much benefit as the baby.

Murdock Liquid Food Co., Boston.

ALETRIS CORDIAL

UTERINE TONIC AND RESTORATIVE.

Prepared from the Aletris Farinosa or True Unicorn and Aromatics.

INDICATIONS.

Amenorrhea, Dysmenorrhea, Leucorrhea, Prolapsus Uteri, Sterility, to Prevent Miscarriage, Etc.

DOSE:—ONE TEASPOONFUL THREE OR FOUR TIMES A DAY.

UNRIVALED AS A UTERINE TONIC IN IRREGULAR, PAINFUL, SUPPRESSED AND EXCESSIVE MENSTRUATION.

It Restores Normal Action to the Uterus, and Imparts Vigor to the Entire Uterine System.

☞Where women have miscarried during previous pregnancies, or in any case where miscarriage is feared, the ALETRIS CORDIAL is indicated, and should be continuously administered during entire gestation.

CHAS. CLAY, M. R. C. S., Manor House, Dewsbury, England, says:—I find Aletris Cordial (Rio) is of great service in threatened miscarriage.

FRANCIS E. CANE, L. R. C. S., &c., Leeds, England, says:—I have tried the Aletris Cordial (Rio) in two cases of long standing dysmenorrhea, with excellent results. One of these patients has spent a week in bed every month for two years. After all the usual remedies, I put her on Aletris Cordial, and for the last two periods she has been out and about all the time.

L. M. WATSON, M. D., Delhi, Ills., says:—I have used Aletris Cordial (Rio) in cases of dysmenorrhea, suppressed menses and threatened miscarriage, and also, combined with Celerina, as a tonic after confinement, with the happiest results, and now I am using it on a case of leucorrhea, with injections of S. H. Kennedy's Extract of Pinus Canadensis, and it is acting like a charm.

P. H. OWEN, M. D., Morganville, Ala., says:—I have prescribed Aletris Cordial (Rio) in several cases with the most satisfactory results, and regard it as the best uterine tonic I have met with in a professional experience of over twenty-five years. In cases of threatened miscarriage it acts like a charm. Would recommend its continuous administration in all cases when there is any indication of miscarriage.

Dr. W. BERTHELOT, Santander, Spain, says:—I have tried the Aletris Cordial (Rio), and it has seemed to me to be useful, especially in cases of dysmenorrhea.

Dr. RASQUINET, Jupile, near Liege, Belgium, says:—I tried Aletris Cordial (Rio) in the case of a woman who had had several miscarriages at the end of five months, and who is now again pregnant, having reached the seventh month: thanks to Aletris Cordial.

R. REECE, M. R. C. S., Walton-on-Thames, England, says:—Aletris Cordial (Rio) in painful menstruation is most valuable. A wife of a minister suffered much, and had had three miscarriages. I prescribed Aletris Cordial. She has for the first time, gone her full time, and was safely confined with a male child.

J. T. COLLIER, M. D., Brooks, Me., says:—I have used your Aletris Cordial (Rio) in cases of females at the menopause. Consider it one of the finest remedies for these cases.

Dr. GORDILLON, St. Amand, France, says: I have tried the Aletris Cordial (Rio) in a case of dysmenorrhea. The result I obtained from the use of your preparation was excellent, better than I had obtained in the same patient by prescribing the usual remedies employed in such cases.

W. F. TOOMBS, M. D., Morrillton, Ark., says:—I have used a great deal of your Aletris Cordial (Rio) and I find it all you claim for it in amenorrhea, dysmenorrhea, metritis, leucorrhea; I don't think it has an equal. I have used it in two cases of threatened miscarriage and the trouble was obviated. For a general Uterine Tonic I know of nothing superior.

R. D. PATTERSON, L. R. C. S. &c., Medical Officer, Caledon Dispensary, Co. Tyrone, Ireland, says:—I have very great pleasure in testifying to the very high opinion I hold of Aletris Cordial (Rio) in threatened miscarriage.

SPORTING AND ATHLETIC GOODS OF EVERY DESCRIPTION.

No Chemicals.

W. BAKER & CO.'S Breakfast Cocoa

Is Absolutely Pure, and it is Soluble.

To increase the solubility of the powdered cocoa, various expedients are employed, most of them being based upon the action of some alkali, potash, soda or even ammonia. Cocoa which has been prepared by one of these chemical processes, can usually be recognized at once by the distinct alkaline reaction of the infusion in water.

W. Baker & Co.'s Breakfast Cocoa is manufactured from the first stage to the last by perfect mechanical processes, **no chemical being used in its preparation.** By one of the most ingenious of these mechanical processes the greatest degree of fineness is secured without the sacrifice of the attractive and beautiful red color which is characteristic of an absolutely pure and natural cocoa.

BOUDAULT'S PEPSINE

The only Pepsine used in the Hospitals of Paris for the last Thirty Years.

Unlike the various substitutes which, in most cases, are but unscientific or incompatible compounds, forced upon the Medical Profession as aids to digestion by extensive advertising, but which, when submitted to the proper tests, are found to be useless as digestive agents, Pepsine is constantly gaining in the esteem of the careful practitioner.

Since the introduction of Pepsine by Boudault and Corvisart in 1854, the original BOUDAULT'S PEPSINE HAS BEEN AT ALL TIMES CONSIDERED THE BEST, as is attested by the awards it has received at the Expositions of 1867, 1868, 187 1873, in 1876 at the Centennial Exposition of Philadelphia, and in 1878 at the Paris Exposition.

The most reliable tests, carefully applied, will satisfy everyone that BOUDAULT'S PEPSINE HAS A MUCH HIGHER DIGESTIVE POWER than the best Pepsines now before the Profession, and is therefore especially worthy of their attention.

BOUDAULT'S PEPSINE is prepared in the form of Pepsine Acid and Pepsine Neutral. It is sold in bottles of one ounce, with a measure containing exactly five grains; also in bottles of four, eight, and sixteen ounces for dispensing.

BOUDAULT'S WINE OF PEPSINE

FORMULA OF DR. CORVISART.

The taste of Pepsine being perfectly disguised in this Wine, it may be recommended to persons who have difficulty in taking Pepsine in the form of Powder. This Wine is tested so that a tablespoonful of it is equal in digestive power to ten grains of Boudault's Pepsine in powder. Sold only in bottles of eight ounces.

TANRET'S PELLETIERINE

For the Treatment of Tape-Worm (Tænia Solium).

This New Tænifuge, the Active Alkaloid of Pomegranate Bark, has of late come into extensive use in France for the treatment of Tape-Worm (Tænia Solium). The results of numerous experiments with it at the Marine Hospitals of Toulon, St. Mandrier, etc., and in the Hospitals of Paris, St. Antoine, La Charité, Necker Beaujon, etc., have all been most satisfactory. Doctor Dujardin Beaumetz, Member of the Academy of Medicine, and Professor Laboulbene, in their report to the Society of Therapeutics, have given it their unqualified approval, after the most searching experiments. This preparation is pleasant to administer, and, if certain preliminaries are observed, success will be insured.

Sold only in bottles containing one dose.

DUCRO'S ALIMENTARY ELIXIR

A Combination uniting the properties of Alcoholic Stimulants and Raw Meat.

This preparation, which has been used with great success in the hospitals of Paris since 1868, is adapted to the treatment o all diseases requiring administration, in a small volume, of a tonic able to stimulate and support the vital forces, as *Pulmonar Phthisis, Depression and Nervous Debility, Adynamia, Malarious Cachexia, etc.*

Prepared by EMILE DURIEZ & CO., Successors to DUCRO & CIE, Paris.

KIRKWOOD'S INHALER

This is the only complete, reliable, and effective inhaler in use, arranged for the direct application of Muriate of Ammonia and other remedial agents in the state of vapor to the diseased parts of the air-passages in the treatment of catarrh and diseases of the throat and lungs. No heat or warm liquids required in its use.

It is entirely different from the various frail, cheap instruments that have been introduced.

KIRKWOOD'S INHALER is accompanied by testimonials of the highest professional character, together with carefully prepared formulas for use.

RETAIL PRICE, COMPLETE, $2.50.

☞ A liberal discount allowed to the trade and profession. For descriptive pamphlet or other information address

THE NEW YORK POLYCLINIC is a School of Clinical Medicine and Surgery for *Practitioners only*. No didactic lectures are given. The classes are limited. The demonstrations are made at the Polyclinic School and Hospital, and in the various Hospitals in New York City with which the Faculty are connected.

Session of 1889–90 opens Monday, September 16th, 1889. For further information and for catalogue, address

JOHN A. WYETH, M.D.,
Secretary of the Faculty,

Or WILLIS O. DAVIS, Clerk,
214, 216 & 218 East 34th Street, New York City.

UNIVERSITY OF MARYLAND
SCHOOL OF MEDICINE.

Eighty-third Annual Announcement, 1889-90. The next regular session will begin October 1st, 1889. A full course of didactic lectures, with ample clinical and dissecting-room facilities.

FACULTY:

GEORGE W. MILTENBERGER, M.D., Professor of Obstetrics.
CHRISTOPHER JOHNSON, M.D., Emeritus Professor of Surgery.
SAMUEL C. CHEW, M.D., Professor of Principles and Practice of Medicine and Hygiene.
FRANK DONALDSON, M.D., Emeritus Clinical Professor of Diseases of the Throat and Chest.
WILLIAM T. HOWARD, M.D., Professor of Diseases of Women and Children and Clinical Medicine.
JULIAN J. CHISOLM, M.D., Professor of Eye and Ear Diseases.
FRANCIS T. MILES, M.D., Professor of Physiology and Clinical Professor of Diseases of Nervous System.
L. McLANE TIFFANY, M.D., Professor of Surgery.
J. EDWIN MICHAEL, M.D., Professor of Anatomy and Clinical Surgery.
I. EDMONSON ATKINSON, M.D., Professor of Materia Medica and Therapeutics, Clinical Medicine and Dermatology.
R. DORSEY COALE, PH.D., Professor of Chemistry and Toxicology.
JOHN NOLAND MACKENZIE, M.D., Clinical Professor of Diseases of the Throat and Nose.
HERBERT HARLAN, M.D., Demonstrator of Anatomy.

For catalogue and further information, address: **Dr. J. EDWIN MICHAEL, Dean, 937 Madison Avenue.**

DENTAL DEPARTMENT.

Eighth Annual Announcement. Next regular session begins October 1st, 1889. New and excellent Infirmary and Laboratory, with abundance of clinical material.

FACULTY:

FRED. J. S. GORGAS, M.D., D.D.S., Professor of Principles of Dental Science, Dental Surgery, and Dental Mechanism.
JAMES H. HARRIS, M.D., D.D.S., Professor of Operative and Clinical Dentistry.
I. EDMONSON ATKINSON, M.D., Professor of Materia Medica and Therapeutics.
FRANCIS T. MILES, M.D., Professor of Physiology.
L. McLANE TIFFANY, M.D., Clinical Professor of Oral Surgery.
J. EDWIN MICHAEL, M.D., Professor of Anatomy.
R. DORSEY COALE, PH.D., Professor of Chemistry.
JOHN C. UHLER, M.D., D.D.S., Demonstrator of Mechanical Dentistry.
CHAS. L. STEEL, M.D., D.D.S., Demonstrator of Operative Dentistry.
HERBERT HARLAN, M.D., Demonstrator of Anatomy.
AND EIGHT ASSISTANT DEMONSTRATORS.

For catalogue and other information, apply to **Dr. F. J. S. GORGAS, Dean, 845 Eutaw Street, Baltimore.**

Medico-Chirurgical College of Philadelphia.

JAS. E. GARRETSON, A.M., M.D., Professor of Oral and Clinical Surgery.
WM. H. PANCOAST, A.M., M.D., Professor of General, Descriptive, and Surgical Anatomy and Clinical Surgery.
GEO. E. STUBBS, A.M., M.D., Professor of Clinical Surgery.
WM. F. WAUGH, A.M., M.D., Professor of Principles and Practice of Medicine and of Clinical Medicine.
ABRAHAM S. GERHARD, A.M., M.D., Professor of Forensic and Clinical Medicine.
WM. S. STEWART, A.M., M.D., Professor of Obstetrics and Clinical Gynecology.
H. EARNEST GOODMAN, M.D., Professor of Principles and Practice of Surgery and Clinical Surgery.
P. D. KEYSER, A.M., M.D., Dean, Professor of Ophthalmology.
SAMUEL B. HOWELL, A.M., M.D., Professor of Chemistry.
JOHN V. SHOEMAKER, A.M., M.D., Professor of Materia Medica, Pharmacology, Therapeutics and Clinical Medicine.
E. E. MONTGOMERY, B.S., M.D., Professor of Gynecology.
JAS. M. ANDERS, Ph.D., M.D., Professor of Hygiene and Clinical Diseases of Children; Associate Professor of Physiology
JOHN V. SHOEMAKER, A.M., M.D., Clinical Professor Skin Diseases.
FRANK WOODBURY, A.M., M.D., Honorary Professor of Clinical Medicine.
WM. B. ATKINSON, A.M., M D. Honorary Professor of Sanitary Science and Paediatrics.

The Regular Session begins September 30th, 1889, and continues until the middle of April. It is preceded by a Preliminary Session of three weeks, and followed by a Spring Session lasting until the middle of June.

Seats are issued in the order of matriculation, and are forfeitable if fees are not paid before November 1st.

Preliminary examination or equivalent degree, and a three years' graded course obligatory. A fourth year voluntary.

Instruction is given by lectures, clinical teaching and practical demonstrations. In the subjects of Anatomy, Pharmacy, Chemistry, Histology and Pathology the usual methods of instruction are largely supplemented by laboratory work.

Examinations are held at the close of each Regular Session upon the studies of the term. Although the degree of Doctor of Medicine is conferred at the end of the third year, a fourth year is earnestly recommended, at the end of which the degree of Doctor of Medicine *cum laude* is given.

FEES.

Matriculation, $5: first and second years, each, $100; third year (no graduation fee), $100; fourth year, free to those who have attended three sessions in this school, to all others, $100.

Extra charges only for material used in the laboratories and dissecting-room.

For further information or announcement, address,

E. E. MONTGOMERY, M.D., Secretary,
Medico-Chirurgical College,
Cherry, below 18th Street, Philadelphia, Penna.

Medical College of Ohio.

Medical Department of the University of Cincinnati.

The Seventy-first Annual Session will begin September 4, 1889, and continue until March 1, 1890.

FEES.—Matriculation Ticket, $5.00; General Lecture Ticket, $75.00; Hospital Ticket, $5.00; Graduation Fee, $25.00.

For circulars, and further information, address

JAMES G. HYNDMAN, M.D., Secretary,
22 West Ninth Street, Cincinnati, Ohio.

WESTERN PENNSYLVANIA MEDICAL COLLEGE

CITY OF PITTSBURGH.

SESSIONS OF 1889—90.

The REGULAR SESSION begins on the last Tuesday of September, and continues six months. During this session, in addition to four Didactic Lectures, two or three hours are daily allotted to Clinical Instruction. Attendance upon two regular courses of lectures is requisite for graduation. A three years' graded course is also provided. The SPRING SESSION embraces recitations, clinical lectures and exercises, and didactic lectures on special subjects; this session begins the second Tuesday in April, and continues ten weeks.

The laboratories are open during the collegiate year for instruction in chemistry, microscopy, practical demonstrations in medical and surgical pathology, and lessons in normal histology. Special importance attaches to "the superior clinical advantages possessed by this College." For particulars, see annual announcement and catalogue, for which, address the Secretary of Faculty, Prof. J. W. J. MCKENNAN.

Business correspondence should be addressed to
PROF. W. J. ASDALE, 2107 Penn Avenue, Pittsburgh.

Woman's Medical College

OF BALTIMORE.

S. E. Cor. Druid Hill Ave. and Hoffman St., Baltimore, Md.

THE EIGHTH ANNUAL SESSION WILL BEGIN ON WEDNESDAY, OCTOBER 2d, 1889.

For further information or catalogue, address
RANDOLPH WINSLOW, M.D., Acting Dean,
No. 1, Mount Royal Terrace, Baltimore, Md.

Medical Department, State University of Iowa, at Iowa City, Iowa.

The next Session will begin on September 11, 1889, and continue until March 12, 1890. Attendance upon three courses of lectures, of six months each, is requisite to graduation. The facilities for dissection and clinical study are unsurpassed.

TERM EXPENSES—Lecture Ticket, $20.00; Demonstrator's Ticket, $10.00; Matriculation Ticket, $5.00 (paid but once); Hospital Ticket, $3.00; Examination Fee (for final examination) $25.00. No charge for dissecting material. For further information, address DR. A. C. PETERS, Ast. Sec'y, Iowa City, Iowa.

College of Physicians and Surgeons of Baltimore, Md.

The Preliminary Course will begin September 15th, 1889. The Regular Session will open October 1st, 1889, and close about March 15th, 1890.

For catalogue containing full information, address
THOMAS OPIE, M. D., Dean,
N. W. Cor. Calvert and Saratoga Sts., Baltimore, Md.

A STENOGRAPHER accustomed to medical work, would like a morning engagement. Surgeon preferred. References unexceptionable. Address, C,

DETROIT COLLEGE OF MEDICINE.

SESSION 1889-90.

Clinical and Practical teaching are made an important feature of this College. Clinical instruction is given daily at HARPER, ST. MARY'S and ST. LUKE'S HOSPITAL, at the COLLEGE, at COLLEGE EYE and EAR INFIRMARY, ST. MARY'S FREE EYE and EAR INFIRMARY, and at the three FREE DISPENSARIES. The facilities offered by this college are unsurpassed for the practical study of MEDICINE, SURGERY, OBSTETRICS, GYNÆCOLOGY, DISEASES OF CHILDREN, GENITO-URINARY, and ORTHOPÆDIC SURGERY, OPHTHALMOLOGY and OTOLOGY, DERMATOLOGY and LARYNGOLOGY.

REGULAR SESSION opens on Wednesday, Sept. 25, and continues six months. During the session, the Professors will take special pains to examine the Students upon the subjects of the previous lectures.

SPRING SESSION begins April 2d, 1890; and closes June 11th.

FEES.—Matriculation fee, $5; Fees for Regular Session, $50; Spring Session, $10, to those who attend the regular term—to all others, $25; Hospital Fee, $10; Graduation Fee, $30; Perpetual Ticket, $100.

For further particulars, and for College Circular, apply to

H. O. WALKER, M.D., Secretary,
33 Lafayette Ave., Detroit, Mich.

UNIVERSITY OF PENNSYLVANIA.—Medical Department.

The 124TH ANNUAL WINTER SESSION will begin Tuesday, October 1st, 1889, at 12 M., and continue until May 1st, 1890.
The PRELIMINARY SESSION begins September 18th, 1889.
The curriculum is graded and three annual winter sessions are required. Practical instruction, including laboratory work in Chemistry, Histology, Osteology and Pathology, with Bedside Instruction in Medicine, Surgery and Gynecology are a part of the regular course and without additional expense.

FACULTY.

JOSEPH LEIDY, M.D., LL.D., Professor of Anatomy.
D. HAYES AGNEW, M.D, LL.D., Honorary Professor of Clinical Surgery.
WILLIAM PEPPER, M.D., LL.D., Professor of Theory and Practice of Medicine, and of Clinical Medicine.
WILLIAM GOODELL, M.D., Professor of Gynecology.
JAMES TYSON, M.D., Professor of Clinical Medicine.
HORATIO C. WOOD, M.D., LL.D, Professor of Materia Medica, Pharmacy and General Therapeutics.
THEODORE G. WORMLEY, M.D., LL.D., Professor of Chemistry and Toxicology.
JOHN ASHHURST, JR., M.D., Professor of Surgery and of Clinical Surgery.
EDWARD T. REICHERT, M.D., Professor of Physiology.
WILLIAM F. NORRIS, M.D., Honorary Prof. of Ophthalmology
BARTON COOKE HIRST, M.D., } Associate Professors of
HOWARD A. KELLY, M.D., } Obstetrics.
J. WILLIAM WHITE, M.D., Professor of Clinical Surgery.
JOHN GUITÉRAS, M.D., Professor of General Pathology and Morbid Anatomy.
GEORGE A. PIERSOL, M.D., Professor of Histology and Embryology.
SAMUEL G. DIXON, M.D., Professor of Hygiene.

For Catalogue and announcement containing particulars, apply to

BUFFALO LITHIA WATER

IN THE TREATMENT OF

ALBUMINURIA, WHETHER OF BRIGHT'S DISEASE, PREGNANCY, OR SCARLET FEVER.

Dr. WM. B. TOWLES, Professor of Anatomy and Materia Medica in the Medical Department of the University of Virginia.

"BUFFALO LITHIA WATER, No. 2, belongs to the ALKALINE OR, *perhaps, to the* ALKALINE-SALINE Class, *for it has proved far more efficacious in many diseased conditions than any of the simple* ALKALINE *waters.*

. . . . . .

"*Its effects are marked in causing a disappearance of* ALBUMEN *from the Urine.* In a single case of BRIGHT'S DISEASE OF THE KIDNEYS I witnessed *decided beneficial results from its use, and from its action in this case I should have great confidence in it as a remedy in certain stages of the disease.*"

Dr. GRAEME M. HAMMOND, of New York, Professor of Diseases of the Mind and Nervous System in the New York Post-Graduate Medical School and Hospital.

"In *all* cases of BRIGHT'S DISEASE of the KIDNEYS I have found BUFFALO LITHIA WATER *of the greatest service in increasing the quantity of urine and in eliminating the* ALBUMEN."

Dr. GEORGE W. MILTENBERGER, Professor of Obstetrics, University of Maryland,

Before the Medical and Chirurgical Faculty of the State of Maryland, recommended BUFFALO LITHIA WATER as an ALKALINE Diuretic in ALBUMINURIA of PREGNANCY.—See *Trans. Faculty of State of Maryland,* 1886.

Dr. WM. H. DOUGHTY, Professor of Materia Medica and Therapeutics, Medical College of Georgia; Member of American Medical Association, etc.

"Over the NAUSEA AND VOMITING OF PREGNANCY, PARTICULARLY IN THE LATTER MONTHS, WHERE URÆMIC CONDITIONS are possibly established, and in PUERPERAL CONVULSIONS, URÆMIA CO-EXISTING, BUFFALO LITHIA WATER often exerts *marked control.*"

Dr. CALEB WINSLOW, 23 McCulloh Street, Baltimore, Member of the Medical and Chirurgical Faculty of Maryland.

"I have found the BUFFALO LITHIA WATER, Spring No. 2, of marked service in relieving the *Nausea of Pregnant Women.* I frequently resort to it at intervals *during the whole course of Pregnancy.* Being *antacid, laxative, diuretic, and tonic, it seems well adapted to relieve the disturbances usually attendant upon Gestation, and I have no doubt its free use might remove* URÆMIC POISON, *and prevent Convulsions produced thereby.*"

Dr. JOS. HOLT, New Orleans, President Board of Health, State of Louisiana.

"I have prescribed BUFFALO LITHIA WATER freely in affections of the *Kidneys* and *Urinary* passages, particularly in GOUTY *subjects.* in ALBUMINURIA, and in irritable conditions of the *Bladder* and *Urethra* in *females.* The results have been such as to satisfy me *of the extraordinary value of this Water in a large class of cases usually most difficult to treat.*"

Dr. JAMES B. McCAW, Professor of the Practice of Medicine in the Virginia Medical College.

[Extract from the Proceedings of the Richmond Academy of Medicine, October 15, 1878.]

"Dr. McCaw also spoke of the great value of BUFFALO LITHIA WATER in ALBUMINURIA of *Scarlet Fever* and in ALBUMINURIA of *Pregnant Women.*"

Dr. J. T. DAVIDSON, New Orleans, La., ex-President New Orleans Surgical and Medical Association.

"I have for several years prescribed BUFFALO LITHIA WATER, Spring No. 2, in all cases of *Scarlet Fever,* directing it to be drunk *ad libitum, with the effect of relieving all traces of* ALBUMEN *in the urine,* and have found it equally efficacious in renal diseases requiring the use of alkaline water."

Dr. G. W. SEMPLE, Hampton, Va., President Medical Society of Virginia.

"In SCARLET FEVER I have known BUFFALO LITHIA WATER *restore a healthy and abundant secretion of Urine, when it was highly charged with* ALBUMEN *and the secretion almost suppressed.*"

Dr. MARTIN L. JAMES, of Richmond, Va., Professor of Materia Medica and Therapeutics, Medical Society of Virginia.

[Proceedings of the Richmond, Virginia, Academy of Medicine, December 16, 1880.]

"The President of the Academy, Dr. M. L. James, reported a case of *Congestion* of the *Kidneys* in a lady eight months advanced in *Pregnancy, attended by marked Œdema,* both over the extremities and surface, and by URÆMIC POISONING *to such an extent as very seriously impaired the vision of the patient,* relieved by the free use of this Water for three weeks.

"Other remedies, he stated, were used in these cases, *but the favorable results seemed clearly attributable to the action of the Water.*"

Dr. HARVEY L. BYRD, of Baltimore, President and Professor of Obsetrics and Diseases of Women and Children in the Baltimore Medical College, formerly Professor of Practical Medicine, etc.

"I have prescribed BUFFALO LITHIA WATER with the most satisfactory results, both as a *remedy* and *prophylactic* in the *Parturient* or *Pregnant Puerperal Eclampsia* or *Convulsions; and I may say that I know of no remedy of equal efficacy with the Water of Spring No. 2 in Sequelæ of Scarlatina.*

"It has an *ascertained value* in BRIGHT'S DISEASE. *A knowledge of its action in that disease thus far would seem* to warrant the belief that it would, in many instances, *at least in its early stages, arrest it entirely, and in its more advanced stage prove a decided comfort and palliative.*

Water in cases of one dozen half-gallon bottles, $5.00 per case at the Springs.

Intestinal Diseases of Children.

"In Cholera Infantum," says Dr. Louis Starr, "the irritability of the stomach is a formidable barrier to alimentation; nevertheless, every effort must be made to give food in small quantities and at short intervals." Clinical experience, the only conclusive test, has proved the great efficacy in this disease, of MELLIN'S FOOD dissolved in water only and given cold, in small amount frequently repeated. "In MELLIN'S FOOD," says Dr. Eustace Smith, "the whole of the starch is converted into dextrine and grape sugar (properly maltose) so that the greater part of the work of digestion is performed before the food reaches the child's stomach." He also says, "I have never seen any signs of fermentation which I could attribute to the influence of maltose." As it is non-fermentable and so quickly assimilated, MELLIN'S FOOD is the best food for infants suffering from this complaint until convalescence has been sufficiently established to allow the regular diet to be resumed.

A sample of MELLIN'S FOOD will be sent to any physician, free of all expense, upon application

SVAPNIA

OR

PURIFIED OPIUM

FOR PHYSICIANS USE ONLY.

Contains the Anodyne and Soporific Alkaloids, Codeia, Narceia and Morphia.

Excludes the Poisonous and Convulsive Alkaloids, Thebaine, Narcotine and Papaverine.

SVAPNIA has been in steadily increasing use for over twenty years, and whenever used has given great satisfaction.

To PHYSICIANS OF REPUTE, not already acquainted with its merits, samples will be mailed on application.

SVAPNIA is made to conform to a uniform standard of Opium of Ten per cent. Morphia strength.

JOHN FARR, Manufacturing Chemist, New York.

C. N. CRITTENTON, Gen'l Agent, 115 Fulton St., N. Y.

To whom all orders for samples must be addressed.

SVAPNIA IS FOR SALE BY DRUGGISTS GENERALLY.

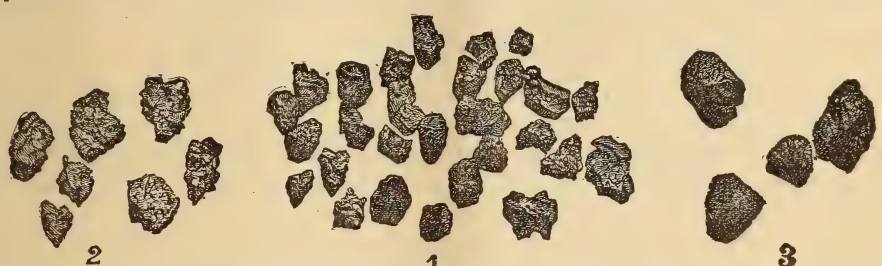
Buffalo Lithia Water

In the TREATMENT OF URINARY DEPOSIT.

Case of Dr. B. J. WEISTLING, of Middleton, Pa., stated by himself.

"Experience in its use in **STONE in the BLADDER** in my own person enables me to attest the efficacy **of the BUFFALO LITHIA WATER** in this painful malady. After having been long subjected to sufferings, the intensity of which cannot be described, I have, under the influence of this Water, passed an ounce of **CALCULI (URIC ACID)**, some of which weighed as much as four grains, affording inexpressible relief and leaving me in a condition of comparative ease and comfort.

"On one occasion I passed thirty-five **CALCULI** in forty-eight hours. The appearance of these **CALCULOUS NUCLEI** indicates unmistakably, I think, that they were all *component particles of one large* **CALCULUS** *destroyed by the action of the Water, by means of solution and disintegration.* At my advanced period of life (I am seventy-seven years and six months of age), and in my feeble general health, a surgical operation was not to be thought of, and the Water seems to have accomplished all that such an operation, if successful, could have done."



[The above plate is from a photograph, and represents the exact size and shape of some of the Calculi passed by Dr. Weistling. They were preserved by his son, Dr. J. Weir Weistling.]

Case stated by Dr. G. HALSTED BOYLAND, late Professor of Surgery, Baltimore Medical College, Member American Medical Association.

"The case of Mr. C., which came under my observation as Resident Physician at the Springs during the season of 1884, affords undoubted evidence that Buffalo Lithia Water is a **SOLVENT** *for Urinary Deposit*, commonly known as **STONE in the BLADDER.** He was operated upon for **STONE,** the operation affording but partial and temporary relief. A year afterward he visited the **BUFFALO LITHIA SPRINGS,** at the same time passing small quantities of a *Urinary Deposit*, of the **TRIPLE PHOSPHATE of AMMONIA** and **MAGNESIA VARIETY,** and his sufferings such as required that he should be kept constantly under the influence of opiates. In some eight weeks the solvent properties of the Water *were evident in the diminished consistency of the deposit, the increased quantity discharged, and by its change from Concrete Lumps to fine Sand,* which he discharged to the amount of *Four Ounces.* After a time, however, the quantity gradually diminished, and finally ceased, and he left the Springs *with the deposit dissolved* and *washed out of the system,* and the *Diathesis fons et origi morbi* altered. There had been a disappearance of the attending distressing symptoms, and great improvement in his general condition."

Dr. MARTIN L. JAMES, of Richmond, Va., Professor of Materia Medica and Therapeutics, Medical Society of Virginia.

[Proceedings of the Richmond, Virginia, Academy of Medicine, December 16, 1880.]

"The President of the Academy, Dr. M. L. James, reported three cases of marked **URIC ACID DIATHESIS** successfully treated by the Water of Spring No. 2 of the **BUFFALO LITHIA SPRINGS** of Virginia. In one of these patients there were, as a result of this Diathesis, **SANDY DEPOSITS** in the *Urine, Inflammation of the Kidneys, Irritability of the Bladder, and Hæmaturia,* and, finally, the passage of a **CALCULUS** of the size of a cherry, formed on a blood-clot as a nucleus. In another case there were frequent attacks of **NEPHRITIC COLIC,** attended by **SANDY DEPOSITIONS in the urine.** After the free use of this Water in these cases, no further manifestations of the disorder occurred."

Dr. HENRY M. WILSON, of Baltimore, ex-President Medical and Chirurgical Faculty of Maryland.

"My experience in the use of the **BUFFALO LITHIA WATER** has not been large, *but it is of such a positive character that I do not hesitate to express my preference for it, as a* **DIURETIC** in **URINARY CALCULI,** *over all other waters that I have ever used.*"

Water in cases of one dozen half-gallon bottles, $5 per case, at the Springs.

THOMAS F. GOODE, Proprietor,

BUFFALO LITHIA SPRINGS, VIRGINIA

Sulfonal-Bayer has been before the Medical Profession for some time, receiving its unqualified endorsement, but the use has been limited in many cases, owing to the hesitation of the practitioner in recommending so costly a remedy.

It is a matter of gratification to us to be able to announce a substantial reduction in price of

THE NEW HYPNOTIC

SULFONAL-BAYER,

which will enable physicians to freely prescribe it whenever indicated, and will bring it within the reach of all classes of patients.

So much has been written and published regarding Sulfonal that it does not here seem necessary to set forth at length its peculiar merits. We have already published two pamphlets on this subject, and the points will be found to be fully exhibited in the series of contributions contained in them. These pamphlets will be mailed to applicants.

Sulfonal was discovered by Prof. Eugen A. Baumann, of Freiburg University, and was first prepared by the Farbenfabriken vorm. Friedr. Bayer & Co., Elberfeld.

Sulfonal-Bayer is supplied by us in half-ounce and one-ounce vials.

We prepare 5-grain and 15-grain Tablets of Sulfonal-Bayer. The tablet form is admirably adapted to the purpose of administering this drug, as when they are placed in the liquids they disintegrate, and are thus received into the system.

We also put up Sulfonal-Bayer in the form of our Soluble Pills, containing 5 grains each.

ANALGESIC—ANTIPYRETIC

PHENACETINE-BAYER.

Phenacetine-Bayer (Para-Acetphenetidine) is a white, glossy, crystalline powder, perfectly tasteless, slightly soluble in water, a little more soluble in glycerine, but most freely in alcohol, and it was first prepared by the Farbenfabriken vorm. Friedr. Bayer & Co., Elberfeld.

Phenacetine-Bayer has been received with great favor by the Medical Profession, and is daily growing in esteem both as an Antipyretic and Analgesic.

Phenacetine-Bayer is an important antineuralgic; its effect is more energetic than that of Antipyrine, and does not cause lassitude or any other disagreeable symptoms.

Our two pamphlets on Phenacetine-Bayer, containing the valuable testimony of eminent physicians, will be mailed on application.

RABUTEAU'S DRAGEES OF IRON

Laureate of the Institute of France.—Prize in Therapeutics.

The studies made by the Physicians of the Hospitals have demonstrated that the **Genuine Dragees of Iron of Rabuteau** are superior to all other preparations of Iron in cases of *Chlorosis, Anæmia, Leucorrhœa, Debility, Exhaustion, Convalescence, Weakness of Children,* and the maladies caused by the Impoverishment and Alteration of the blood after periods of fatigue, watching, and excesses of any kind.

TAKE 4 TO 6 DRAGEES DAILY.

Rabuteau's Elixir of Iron is recommended to those persons who may be unable to swallow the Dragees. Dose —*A small wineglassful with meals.*

Rabuteau's Syrup of Iron is specially designed for children. Chalybeate medication, by means of **Rabuteau's Iron,** is the most economical and the most rational known to therapeutics.

No constipation, no diarrhœa, complete assimilation.

Take only the GENUINE IRON OF RABUTEAU of

CLIN & CO., Paris.

SOLUTION OF THE SALICYLATE OF SODA OF DOCTOR CLIN.

Laureate of the Paris Faculty of Medicine (MONTYON PRIZE).

Dr. Clin's Solution, always identical in its composition, and of an agreeable taste, permits the easy administration of *pure Salicylate of Soda,* and the variation of the dose in accordance with the indications presented.

"The *Salicylate of Soda* used by **Clin** is of perfect purity, "and is prepared with the greatest care; it is a medicament "in which we may have every confidence."

—*Paris Society of Medicine, Meeting of Feb. 8th, 1879.*

Clin's Solution, very exactly mixed, contains: 2 grammes of *Salicylate of Soda* per tablespoonful, 50 centigrammes of *Salicylate of Soda* per teaspoonful.

"Aconitine produces marvelous effects in the treatment "of *facial neuralgias* when they are not symptomatic of "intracranial tumor."—*Society of Biology of Paris, Meeting* "*of the 28th February, 1880.*

DOSE—Take 3 to 6 pills during the twenty-four hours.

ACCEPT ONLY THE GENUINE MOUSSETTE PILLS OF

CLIN & CO.,—Paris.

GRAND NATIONAL PRIZE OF 16,600 FRANCS,

QUINA-LAROCHE

This meritorious **Elixir, QUINA-LAROCHE,** is prepared from the **three** Cinchonas; it is an agreeable and doubtless highly efficacious remedy.

—*The Lancet.*

VINOUS ELIXIR,

A STIMULATING RESTORATIVE

—AND—

ANTI-FEBRILE TONIC.

QUINA-LAROCHE under the form of a vinous **Elixir** contains the totality of the numerous principles of the **three** Cinchona barks. It is a preparation which renders great services to Therapeutics.—Extract of the *Gazette des Hôpitaux,* Paris.

FAR SUPERIOR TO ALL ORDINARY CINCHONA WINES.

LAROCHE'S QUINA, tried by the Academy of Medicine of Paris, is a specially prepared COMPOUND EXTRACT of Quinquina, a careful analysis, confirmed by experience, has shown that most of the wines and syrups hitherto used have not contained all the properties of this precious bark, of these some, although beneficial, are altogether lost, while many preparations contain but half the properties of the bark in varying proportions.

MR. LAROCHE, by his peculiar method, has succeeded in extracting all the active principles of the quinquina, combining these with *Catalan Wine* forming an Elixir free from the disagreeable bitterness of other similar preparations. Practitioners have found triple advantages in the use of this Elixir, it is a *strong tonic,* is easily administered, and perfectly harmless, being free from the unpleasant effects of Quinine.

THE FERRUGINOUS QUINA-LAROCHE is the invigorating tonic *par excellence,* having the advantage of being easily assimilated by the gastric juice; without, in any way, deranging the action of the digestive organs, proving itself to be a most efficacious remedy in cases of impoverishment of the blood, ANÆMIA, CHLOROSIS, INTESTINAL HÆMORRHAGE, CASTRALGIA, EXHAUSTION, ETC., ETC.

PARIS.—22 RUE DROUOT.—PARIS.

BROMIDIA

THE HYPNOTIC.

FORMULA.—

Every fluid drachm contains 15 grains EACH of Pure Chloral Hydrat. and purified Brom. Pot., and one-eighth grain EACH of gen. imp. ext. Cannabis Ind. and Hyoscyam.

DOSE.—

One-half to one fluid drachm in WATER or SYRUP every hour, until sleep is produced.

INDICATIONS.—

Sleeplessness, Nervousness, Neuralgia, Headache, Convulsions, Colic, Mania, Epilepsy, Irritability, etc. In the restlessness and delirium of fevers it is absolutely invaluable.

IT DOES NOT LOCK UP THE SECRETIONS.

PAPINE

THE ANODYNE.

Papine is the Anodyne or pain-relieving principle of Opium, the Narcotic and Convulsive Elements being eliminated. It has less tendency to cause Nausea, Vomiting, Constipation, Etc.

INDICATIONS.—

Same as Opium or Morphia.

DOSE.—

(ONE FLUID DRACHM)—represents the Anodyne principle of one-eighth grain of Morphia.

IODIA

The Alterative and Uterine Tonic.

FORMULA.—

Iodia is a combination of active principles obtained from the Green Roots of Stillingia, Helonias, Saxifraga, Menispermum, and Aromatics. Each fluid drachm also contains five grains Iod. Potas., and three grains Phos. Iron.

DOSE.—

One or two fluid drachms (more or less as indicated) three times a day before meals.

INDICATIONS.—

Syphilitic, Scrofulous and Cutaneous Diseases, Dysmenorrhea, Menorrhagia, Leucorrhea, Amenorrhea, Impaired Vitality, Habitual Abortions, and General Uterine Debility.

A Peerless Chemico-Physiological Food and Restorative

Crystalline Phosphate

A TISSUE FOOD

PHOSPHATIC FOOD PRODUCTS TRADE MARK

Contains all essential inorganic components of the tissues in a semi-solid, easily soluble, crystalline mass,

COMPOSED OF

ACID PHOSPHATE OF CALCIUM.

WITH

Acid Phosphate of Magnesium,
" " " Iron,
" " " Sodium,
" " " Potassium,
Chloride of Potassium,
" " Sodium
Sulphate of Potassium,
and Phosphoric acid.

INDICATIONS:

STOMACH DISORDERS, such as Indigestion, Flatulence Gastric Catarrh, and Poor Appetite, Constipation, etc.

WRONGS OF NUTRITION, as in Scrofula, Rickets, Caries, Marasmus, Delayed Union of Fractures, Necrosis of Tissue, Difficult or Delayed Dentition and Development, etc.

NERVOUS AND GENERAL DEBILITY AND SLEEPLESSNESS, as from Sexual Excess, Venerial Disease, Childbearing, Nursing, Loss of Blood or other fluids, Menstrual and other Diseases of Women, abuse of Alcohol, Tobacco and Narcotics, Protracted Illness, etc.

PROF. KONN B. SAYRES, M. D., Demonstrator of Anatomy, Miami Medical College, Cincinnati, O.

I am pleased to inform you that I have during about six months last past made a critical trial of your **Crystalline Phosphate,** in various cases of mal-nutrition, nervous prostration, atonic dyspepsia, insomnia and kindred derangements of the vital functions, which has demonstrated the fact that it is a preparation of *very great value.* I believe your representations concerning it are fully justified by actual and palpable results in my practice, and I very cheerfully recommend it, knowing that a fair trial will prove it worthy of the confidence of the profession.

LENTZ'S
NEW COMPACT
OPERATING SET
No. 10.

One Amputating Knife (Leg and Arm). One Finger Knife. One Hernia Knife. One Sharp Curved Bistoury. Two Scalpels. One Tenotome. One Tenaculum. One pair Scissors, curved or flat. One Saw, 9-inch blade. One Liston's Spring Bone Forceps. One Artery and Needle Forceps, improved. One Dressing Forceps. One Esmarch's Flat Rubber Tourniquets, with Chain. One Director, with Aneurism Needle. Two Silver Probes. Silk, Wire, Wax, and Needles.

The above instruments are put up in a fine Morocco Case with nickel trimmings, lined with velvet, and has extra space for Trephine and Elevator, if desired. With the *sixteen* instruments contained in this case, any ordinary operation may be performed.

Size, 11 in. long, 4 in. wide, 2 in. high

Price, $25. With Trephine and Handle and Trephine Elevator in addition, $29.65. We also make the above case with hard rubber antiseptic handles on knives and saw. Price, $29.00. With Trephine and Elevator in addition, $33.65.

Discount 25 pr. ct. to Physicians

Our New Catalogue of 260 pages will be sent on receipt of 10 cents for postage.

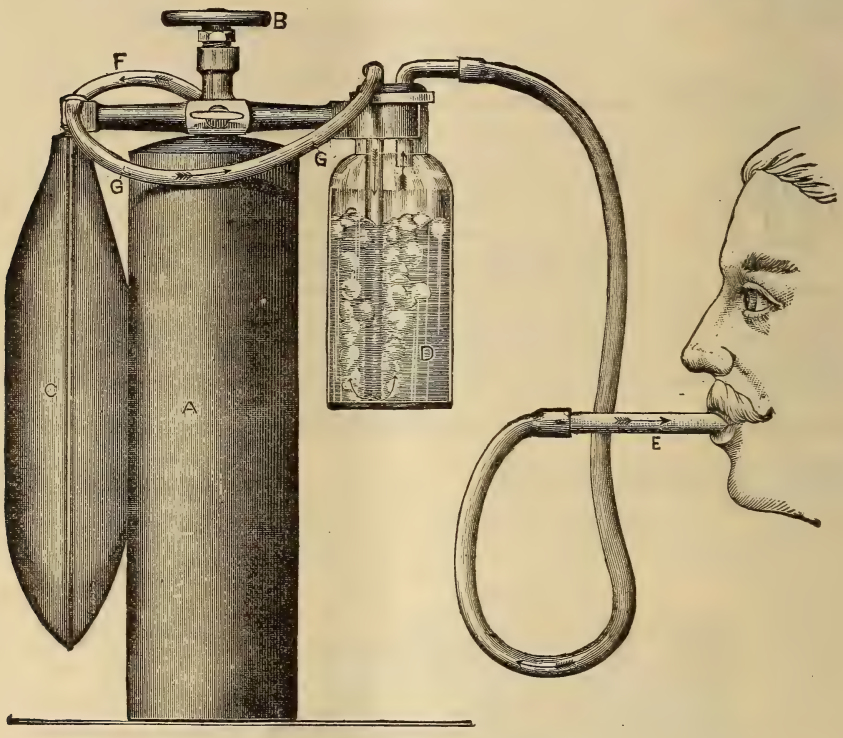
Established 1866. **Philadelphia.**

INHALATION APPARATUS

FOR

THE THERAPEUTIC ADMINISTRATION OF OXYGEN.



In the treatment of lung troubles by Oxygen its exhibition by inhalation is preferred. The apparatus herewith shown is a modification of the Nitrous Oxide apparatus which we have supplied for many years. It is made in the best manner throughout, and is the outcome of years of experience in the manufacture of gas apparatus. It will be found to meet all the requirements.

We supply the gas in two sizes of cylinders, containing respectively forty and one hundred gallons, either pure Oxygen, or a mixture of Oxygen and Nitrous Oxide in definite proportions of 20 per cent., and forty per cent. of Nitrous Oxide.

Whether pure or mixed the gas is sold at the uniform price of 5 cents a gallon. The cost of the cylinders will be refunded on their return empty with the valves in good condition. Full description of Inhalation and Enema apparatuses with directions for use accompany each apparatus, or will be supplied on application.

PRICES.

Inhalation Apparatus	$5.00
Cylinder, 40 gallons' capacity	6.00
40 gallons Gas, either pure Oxygen or mixed Oxygen and Nitrous Oxide	2.00
Complete Apparatus, Cylinder, and 40 gallons Gas	$13.00
Inhalation Apparatus	$5.00
Cylinder, 100 gallons' capacity	15.00
100 gallons Gas, either pure or mixed	5.00
Complete Apparatus, Cylinder, and 100 gallons Gas	$25.00

THE BEST ANTISEPTIC
FOR BOTH INTERNAL AND EXTERNAL USE.

ANTISEPTIC, PROPHYLACTIC, DEODORANT.

LISTERINE

NON-TOXIC, NON-IRRITANT, NON-ESCHAROTIC.

FORMULA—Listerine is the essential antiseptic constituent of Thyme, Eucalyptus, Baptisia, Gaultheria and Mentha Arvensis, in combination. Each fluid drachm also contains two grains of refined and purified Benzo-boracic Acid.

DOSE—Internally: One teaspoonful three or more times a day (as indicated) either full strength, or diluted, as necessary for varied conditions.

LISTERINE is a well-proven antiseptic agent—an antizymotic—especially adapted to internal use, and to make and maintain surgical cleanliness—asepsis—in the treatment of all parts of the human body, whether by spray, irrigation, atomization, or simple local application, and therefore characterized by its particular adaptability to the field of

PREVENTIVE MEDICINE—INDIVIDUAL PROPHYLAXIS.

Diseases of the Uric Acid Diathesis.
LAMBERT'S
LITHIATED HYDRANGEA
KIDNEY ALTERATIVE—ANTI-LITHIC.

FORMULA—Each fluid drachm of "Lithiated Hydrangea" represents thirty grains of FRESH HYDRANGEA and three grains of CHEMICALLY PURE Benzo-Salicylate of Lithia. Prepared by our improved process of osmosis, it is INVARIABLY of DEFINITE and UNIFORM therapeutic strength, and hence can be depended upon in clinical practice.

DOSE—One or two teaspoonfuls four times a day (preferably between meals).

Urinary Calculus, Gout, Rheumatism, Bright's Disease, Diabetes, Cystitis, Hæmaturia Albuminuria, and Vesical irritations generally.

We have much valuable literature upon { GENERAL ANTISEPTIC TREATMENT, LITHEMIA, DIABETES, CYSTITIS, ETC. } To forward to Physicians upon request.

Geo Hamlin Pres't. Chas Roome Parmele Treas.

GENTLEMEN:

The Case of your wines sent me for analysis by Dr. A. L. Hummel, of the "Annals of Hygiene," containing specimens of your La Rosa Zinfandel, Mataro, Riesling, Royal Tokay, and Royal Grape Brandy, has been duly received.

I have examined them for the common contaminants of wine; to wit: Sulphurous acid and sulphites, salicylic acid, fuchsin, lead salts, etc., none of which I found present therein.

I have also determined their alcoholic strength, extractives, and ashes, and found them to correspond strictly in this respect with the standard of pure and natural wines, which cannot be said of many of the imported wines.

As a native of a wine-producing country, I consider myself somewhat of a judge of wines, and regard your products as comparing more than favorably with most of the wines from abroad which are sold at higher prices, so much so that I enclose within my order for fifty bottles of La Rosa Zinfandel, which I expect to use hereafter exclusively at my table.

Very Respectfully,

L. WOLFF, M.D.,
Demonstrator of Chemistry, Jefferson Medical College.

THE SUSTAINED SUPREMACY

OF

Fairchild's Pepsin,

In ACTIVITY, PERMANENCE and GENERAL EXCELLENCE

Has won for this product a wide use and recognition in all the principal markets of the world.

We guarantee it to be unchangeable, to maintain its activity and quality under all ordinary commercial conditions; it is therefore, by far the most available for the dispensing counter, as well as in the manufacture of every form of pepsin preparation.

Under exactly parallel conditions, with any proper percentage of acidity and with any proportion of such acidulated water to the albumen, Fairchild's pepsin is positively superior to any pepsin known.

It will, under absolutely comparative conditions, grain for grain, digest more albumen than any other pepsin made.

We will be pleased to send samples to any physician who may wish to ascertain for himself the relative activity of Fairchild's pepsin, or to submit it to any practical trial.

Prices and complete information upon application.

FAIRCHILD BROS. & FOSTER,

New York. Chicago. London.

Intestinal Diseases of Children.

"In Cholera Infantum," says Dr. Louis Starr, "the irritability of the stomach is a formidable barrier to alimentation; nevertheless, every effort must be made to give food in small quantities and at short intervals." Clinical experience, the only conclusive test, has proved the great efficacy in this disease, of MELLIN'S FOOD dissolved in water only and given cold, in small amount frequently repeated. "In MELLIN'S FOOD," says Dr. Eustace Smith, "the whole of the starch is converted into dextrine and grape sugar (properly maltose) so that the greater part of the work of digestion is performed before the food reaches the child's stomach." He also says, "I have never seen any signs of fermentation which I could attribute to the influence of maltose." As it is non-fermentable and so quickly assimilated, MELLIN'S FOOD is the best food for infants suffering from this complaint until convalescence has been sufficiently established to allow the regular diet to be resumed.

A sample of MELLIN'S FOOD will be sent to any physician, free of all expense, upon application.

DOLIBER-GOODALE CO., Boston, Mass.

This Label will henceforth also serve to distinguish the HUNGARIAN APERIENT WATER SOLD BY THE COMPANY from all other Aperient Waters.

DEMAND THE 
DIAMOND MARK.

And insist upon receiving the HUNGARIAN APERIENT WATER of the APOLLINARIS COMPANY, LIMITED, London.

THE VALUE OF NUTRITION IN DISEASE.

All physicians who have ever used Murdock's Liquid Food and Suppositories recognize their value over all other foods, in breaking up disease and building up the patients after disease, preventing a relapse, **as the same results are obtained as in surgery.** Its value in surgical cases we illustrate by the records of the different cities and of Murdock's Free Surgical Hospital for Women, which is the largest in the United States. It contains 114 beds, every bed free, including operation, the operations ranging from 1000 to 1200 yearly, representing 90 of the worst classes known in surgery. Among these cases we have had **Cancer of uterus** (*Kolpo-hysterectomy*), 13; **Salpingitis** (*Tait's operation*), 31; **Fibroid of uterus** (*abdominal hysterectomy*), 19; **Ventral operation, hernia,** (*abdominal section*), 12; **Cancer of bowel** (*incision*), 2; **Parovarian cyst, 6; Papillomatous cyst** (*extirpation*), 4; **Tubercular peritonitis** (*incision*), 1; **Ovarian cystoma 27; Nymphomania** (*Battey*), 1; **Exploratory abdominal incisions, 12; Fibroid with abdominal abscess** (*Hegar*), 2; **Hysterorraphy, 2; Dermoid cyst, 3; Cirrhotic ovaries,** (*Battey*), 4; **Fibroid uterus** (*Hegar*), 6; **Hystero-epilepsy** (*Battey*), 1; **Haemato-Salpinx** (*Tait*), 5; **Rupture of intestine into vagina, 1; Dislocated kidney, 2; Fibroid tumor abdominal wall, 1; Resection of intestine** (*Senn*), 1; **Ruptured perineum, 294.** Patients are in the Hospital 8 days before and 26 days after operation, on an average.

In Boston, last year, 42 deaths were from Cancer in the Breast. In Murdock's Hospital, 35 such cases were operated on without a death, the patients remaining in the Hospital, on an average, 18 days.

Mortality in Boston,	25.60	per	1000.
" of Women in Boston,	29,00	"	"
" in **Murdock's Free Surgical Hospital,**	**5.00**	"	"
" New York,	26.32	"	"
" Philadelphia,	20.00	"	"
" Chicago,	20.90	"	"
" St. Louis,	20.49	"	"

showing our mortality is only one-sixth as great as of those in health. As good results were obtained in our General Hospital, which we kept open 27 months, **thus showing the value of nutrition as found in Murdock's Liquid Food, and so recognized by the British and American Medical Associations,** before which essays were read and discussed, and it is the only Raw food preparation on which essays were ever read.

Physicians are invited to visit our Hospitals and Works, also to send in patients and to be present at the operations. For any physician who has not used our Liquid Food (and Suppositories for adults and infants), we will deliver free samples to any express company in Boston.

When babies do not thrive, never change their food, but add five or more drops at each feeding of Murdock's Liquid Food, and their lost or needed vitality will be restored in less than thirty days. It is invaluable when weaning babies or when teething. If mothers will take one teaspoonful to a tablespoonful before each meal and on retiring, they will receive as much benefit as the baby.

Murdock Liquid Food Co., Boston.

CELERINA

NERVE TONIC, STIMULANT AND ANTISPASMODIC.

FORMULA.—Every Fluid Drachm represents FIVE grains EACH—Celery, Coca, Kola, Viburnum and Aromatics.

INDICATIONS.—Loss of Nerve-Power (so usual with Lawyers, Preachers, Writers and Business Men), Impotency, Spermatorrhea, Nervous Headache, Neuralgia, Paralysis, Hysteria, Opium Habit, Inebriety, Dyspepsia, and ALL LANGUID conditions of the System.

Indispensable to restore a patient after alcoholic excess.

DOSE.—One or two Teaspoonfuls three or more times a day, as directed by the Physician.

LIQUID IRON-RIO

Palatable and easily assimilated. Does not produce Nausea, nor irritate the Stomach. Does not Cause Headache, nor Constipate. Does not Stain the Teeth. It is so Acceptable to the Stomach that its Use is Admissible when all other forms of Iron would be rejected. Being so Readily Assimilable, it only requires a small Dose.

Each Fluid Drachm contains ONE GRAIN of Iron in a Pleasant and Digestible Form.

DOSE.—One or more Teaspoonfuls as indicated, during or after meals.

S. H. KENNEDY'S

CONCENTRATED EXTRACT OF

PINUS CANADENSIS

DARK. A NON-ALCOHOLIC LIQUID. WHITE.

A MOST VALUABLE NON-IRRITATING MUCOUS ASTRINGENT.

INDICATIONS.—Albuminuria, Diarrhea, Dysentery, Night-Sweats, Hemorrhages, Profuse Expectoration, Catarrh, Sore Throat, Leucorrhea, and other Vaginal Diseases, Piles, Sores, Ulcers, Burns, Scalds, Gonorrhea, Gleet, Etc.

When Used as an Injection, to Avoid Staining of Linen, the WHITE Pinus should be used.

RECOMMENDED BY PROMINENT EUROPEAN AND AMERICAN PHYSICIANS.

PHILADELPHIA.

SPORTING AND ATHLETIC GOODS OF EVERY DESCRIPTION.

No Chemicals.

W. BAKER & CO.'S Breakfast Cocoa

Is Absolutely Pure, and it is Soluble.

To increase the solubility of the powdered cocoa, various expedients are employed, most of them being based upon the action of some alkali, potash, soda or even ammonia. Cocoa which has been prepared by one of these chemical processes, can usually be recognized at once by the distinct alkaline reaction of the infusion in water.

W. Baker & Co.'s Breakfast Cocoa is manufactured from the first stage to the last by perfect mechanical processes, **no chemical being used in its preparation.** By one of the most ingenious of these mechanical processes the greatest degree of fineness is secured without the sacrifice of the attractive and beautiful red color which is characteristic of an absolutely pure and natural cocoa.

BOUDAULT'S PEPSINE

The only Pepsine used in the Hospitals of Paris for the last Thirty Years.

Unlike the various substitutes which, in most cases, are but unscientific or incompatible compounds, forced upon the Medical Profession as aids to digestion by extensive advertising, but which, when submitted to the proper tests, are found to be useless as digestive agents, Pepsine is constantly gaining in the esteem of the careful practitioner.

Since the introduction of Pepsine by Boudault and Corvisart in 1854, the original BOUDAULT'S PEPSINE HAS BEEN AT ALL TIMES CONSIDERED THE BEST, as is attested by the awards it has received at the Expositions of 1867, 1868, 187 1873, in 1876 at the Centennial Exposition of Philadelphia, and in 1878 at the Paris Exposition.

The most reliable tests, carefully applied, will satisfy everyone that BOUDAULT'S PEPSINE HAS A MUCH HIGHER DIGESTIVE POWER than the best Pepsines now before the Profession, and is therefore especially worthy of their attention.

BOUDAULT'S PEPSINE is prepared in the form of Pepsine Acid and Pepsine Neutral. It is sold in bottles of one ounce, with a measure containing exactly five grains; also in bottles of four, eight, and sixteen ounces for dispensing.

BOUDAULT'S WINE OF PEPSINE

FORMULA OF DR. CORVISART.

The taste of Pepsine being perfectly disguised in this Wine, it may be recommended to persons who have difficulty in taking Pepsine in the form of Powder. This Wine is tested so that a tablespoonful of it is equal in digestive power to ten grains of Boudault's Pepsine in powder. Sold only in bottles of eight ounces.

TANRET'S PELLETIERINE

For the Treatment of Tape-Worm (Tænia Solium).

This New Tænifuge, the Active Alkaloid of Pomegranate Bark, has of late come into extensive use in France for the treatment of Tape-Worm (Tænia Solium). The results of numerous experiments with it at the Marine Hospitals of Toulon, St. Mandrier, etc., and in the Hospitals of Paris, St. Antoine, La Charité, Necker Beaujon, etc., have all been most satisfactory. Doctor Dujardin Beaumetz, Member of the Academy of Medicine, and Professor Laboulbene, in their report to the Society of Therapeutics, have given it their unqualified approval, after the most searching experiments. This preparation is pleasant to administer, and, if certain preliminaries are observed, success will be insured.

Sold only in bottles containing one dose.

DUCRO'S ALIMENTARY ELIXIR

A Combination uniting the properties of Alcoholic Stimulants and Raw Meat.

This preparation, which has been used with great success in the hospitals of Paris since 1868, is adapted to the treatment of all diseases requiring administration, in a small volume, of a tonic able to stimulate and support the vital forces, as *Pulmonar Phthisis, Depression and Nervous Debility, Adynamia, Malarious Cachexia, etc.*

Prepared by EMILE DURIEZ & CO., Successors to DUCRO & CIE, Paris.

KIRKWOOD'S INHALER

This is the only complete, reliable, and effective inhaler in use, arranged for the direct application of Muriate of Ammonia and other remedial agents in the state of vapor to the diseased parts of the air-passages in the treatment of catarrh and diseases of the throat and lungs. No heat or warm liquids required in its use.

It is entirely different from the various frail, cheap instruments that have been introduced.

KIRKWOOD'S INHALER is accompanied by testimonials of the highest professional character, together with carefully prepared formulas for use.

RETAIL PRICE, COMPLETE, $2.50.

☞ A liberal discount allowed to the trade and profession. For descriptive pamphlet or other information address

JOHN V. SHOEMAKER, A.M., M.D., Clinical Professor Skin Diseases.

FRANK WOODBURY, A.M., M.D., Honorary Professor of Clinical Medicine.

WM. B. ATKINSON, A.M., M.D. Honorary Professor of Sanitary Science and Paediatrics.

The Regular Session begins September 30th, 1889, and continues until the middle of April. It is preceded by a Preliminary Session of three weeks, and followed by a Spring Session lasting until the middle of June.

Seats are issued in the order of matriculation, and are forfeitable if fees are not paid before November 1st.

Preliminary examination or equivalent degree, and a three years' graded course obligatory. A fourth year voluntary.

Instruction is given by lectures, clinical teaching and practical demonstrations. In the subjects of Anatomy, Pharmacy, Chemistry, Histology and Pathology the usual methods of instruction are largely supplemented by laboratory work.

Examinations are held at the close of each Regular Session upon the studies of the term. Although the degree of Doctor of Medicine is conferred at the end of the third year, a fourth year is earnestly recommended, at the end of which the degree of Doctor of Medicine *cum laude* is given.

FEES.

Matriculation, $5: first and second years. each, $100; third year (no graduation fee), $100; fourth year, free to those who have attended three sessions in this school, to all others, $100.

Extra charges only for material used in the laboratories and dissecting-room.

For further information or announcement, address,

E. E. MONTGOMERY, M.D., Secretary,
Medico-Chirurgical College,
Cherry, below 18th Street, Philadelphia, Penna.

Medical College of Ohio.

Medical Department of the University of Cincinnati.

The Seventy-first Annual Session will begin September 4, 1889, and continue until March 1, 1890.

FEES.—Matriculation Ticket, $5.00; General Lecture Ticket, $75.00; Hospital Ticket, $5.00; Graduation Fee, $25.00.

For circulars, and further information, address
JAMES G. HYNDMAN, M.D., Secretary,
22 West Ninth Street, Cincinnati, Ohio.

WESTERN PENNSYLVANIA MEDICAL COLLEGE

CITY OF PITTSBURGH.

SESSIONS OF 1889—90.

The REGULAR SESSION begins on the last Tuesday of September, and continues six months. During this session, in addition to four Didactic Lectures, two or three hours are daily allotted to Clinical Instruction. Attendance upon two regular courses of lectures is requisite for graduation. A three years' graded course is also provided. The SPRING SESSION embraces recitations, clinical lectures and exercises, and didactic lectures on special subjects; this session begins the second Tuesday in April, and continues ten weeks.

The laboratories are open during the collegiate year for instruction in chemistry, microscopy, practical demonstrations in medical and surgical pathology, and lessons in normal histology. Special importance attaches to "the superior clinical advantages possessed by this College." For particulars, see annual announcement and catalogue, for which, address the Secretary of Faculty, Prof. J. W. J. McKENNAN.

Business correspondence should be addressed to
PROF. W. J. ASDALE, 2107 Penn Avenue, Pittsburgh.

Woman's Medical College
OF BALTIMORE.

S. E. Cor. Druid Hill Ave. and Hoffman St., Baltimore, Md.

THE EIGHTH ANNUAL SESSION WILL BEGIN ON WEDNESDAY, OCTOBER 2d, 1889.

For further information or catalogue, address
RANDOLPH WINSLOW, M.D., Acting Dean,
No. 1, Mount Royal Terrace, Baltimore, Md.

Medical Department, State University of Iowa,
at Iowa City, Iowa.

The next Session will begin on September 11, 1889, and continue until March 12, 1890. Attendance upon three courses of lectures, of six months each, is requisite to graduation. The facilities for dissection and clinical study are unsurpassed.

TERM EXPENSES—Lecture Ticket, $20.00; Demonstrator's Ticket, $10.00; Matriculation Ticket, $5.00 (paid but once); Hospital Ticket, $3.00; Examination Fee (for final examination) $25.00. No charge for dissecting material. For further information, address DR. A. C. PETERS, Ast. Sec'y, Iowa City, Iowa.

College of Physicians and Surgeons
of Baltimore, Md.

The Preliminary Course will begin September 15th, 1889. The Regular Session will open October 1st, 1889, and close about March 15th, 1890.

For catalogue containing full information, address
THOMAS OPIE, M. D., Dean,
N. W. Cor. Calvert and Saratoga Sts., Baltimore, Md.

DETROIT COLLEGE OF MEDICINE.

SESSION 1889-90.

Clinical and Practical teaching are made an important feature of this College. Clinical instruction is given daily at HARPER, ST. MARY'S and ST. LUKE'S HOSPITAL, at the COLLEGE, at COLLEGE EYE and EAR INFIRMARY, ST. MARY'S FREE EYE and EAR INFIRMARY, and at the three FREE DISPENSARIES. The facilities offered by this college are unsurpassed for the practical study of MEDICINE, SURGERY, OBSTETRICS, GYNÆCOLOGY, DISEASES OF CHILDREN, GENITO-URINARY, and ORTHOPÆDIC SURGERY, OPHTHALMOLOGY and OTOLOGY, DERMATOLOGY and LARYNGOLOGY.

REGULAR SESSION opens on Wednesday, Sept. 25, and continues six months. During the session, the Professors will take special pains to examine the Students upon the subjects of the previous lectures.

SPRING SESSION begins April 2d, 1890; and closes June 11th.

FEES.—Matriculation fee, $5; Fees for Regular Session, $50; Spring Session, $10, to those who attend the regular term—to all others, $25; Hospital Fee, $10; Graduation Fee, $30; Perpetual Ticket, $100.

For further particulars, and for College Circular, apply to

H. O. WALKER, M.D., Secretary,
33 Lafayette Ave., Detroit, Mich.

UNIVERSITY OF PENNSYLVANIA.—Medical Department.

The 124TH ANNUAL WINTER SESSION will begin Tuesday, October 1st, 1889, at 12 M., and continue until May 1st, 1890.
The PRELIMINARY SESSION begins September 18th, 1889.
The curriculum is graded and three annual winter sessions are required. Practical instruction, including laboratory work in Chemistry, Histology, Osteology and Pathology, with Bedside Instruction in Medicine, Surgery and Gynecology are a part of the regular course and without additional expense.

FACULTY.

JOSEPH LEIDY, M.D., LL.D., Professor of Anatomy.
D. HAYES AGNEW, M.D, LL.D., Honorary Professor of Clinical Surgery.
WILLIAM PEPPER, M.D., LL.D., Professor of Theory and Practice of Medicine, and of Clinical Medicine.
WILLIAM GOODELL, M.D., Professor of Gynecology.
JAMES TYSON, M.D., Professor of Clinical Medicine.
HORATIO C. WOOD, M.D., LL.D, Professor of Materia Medica, Pharmacy and General Therapeutics.
THEODORE G. WORMLEY, M.D., LL.D., Professor of Chemistry and Toxicology.
JOHN ASHHURST, JR., M.D., Professor of Surgery and of Clinical Surgery.
EDWARD T. REICHERT, M.D., Professor of Physiology.

ELIXIR COCA AND CALISAYA

(S. & O.)

A valuable nerve stimulant and tonic, entirely different from any other preparation of Coca or Calisaya. Made by a process which brings out in the highest degree the active principles of fresh

COCA LEAVES AND CINCHONA BARK.

Free from bitter taste or depressing effects after using. It is recommended to physicians as useful in Atonic Indigestion, Insomnia, Nervous Exhaustion, Mental Depression, etc.

Made only by

STRYKER & OGDEN,

Walnut and 13th Streets, Philadelphia.

PHYSICIANS' OFFICE AND OPERATING

COATS.

MADE OF BLEACHED DRILLING;
WILL NOT SHRINK IN WASHING.

$1.25 each; $7.00 per ½ Dozen.

Single Coats by Post, 15 cents additional.

HIRSH, FRANK & CO.,

31 North Third St., Philadelphia.

☞In ordering, send chest measure and length of sleeve from middle of back.

The only prominent Emulsion of Cod-Liver Oil introduced directly to the medical profession. It is advertised exclusively in medical journals.

HYDROLEINE.

(HYDRATED OIL.)

Produces rapid increase in Flesh and Strength.

FORMULA.—Each Dose contains:			
Pure Cod Liver Oil.....80 m. (drops)		Soda.....1-3 Grains	
Distilled Water.....35 "		Salicylic Acid.....1-4 "	
Soluble Pancreatin..... 5 Grains.		Hyocholic Acid.....1-80 "	

Recommended and Prescribed by EMINENT PHYSICIANS Everywhere. It is pleasant to the Taste and acceptable to the most delicate Stomach.

IT IS ECONOMICAL IN USE AND CERTAIN IN RESULTS.

HYDROLEINE (Hydrated Oil) is not a simple alkaline emulsion of oleum morrhuæ, but a hydro-pancreated preparation, containing acids and a small percentage of soda. Pancreatin is the digestive principle of fatty foods, and in the soluble form here used, readily converts the oleaginous material into assimilable matter, a change so necessary to the reparative process in all wasting diseases.

The following are some of the diseases in which **HYDROLEINE** is indicated:

Phthisis, Tuberculosis, Catarrh, Cough, Scrofula, Chlorosis, General Debility, etc.

TO BRAIN WORKERS of all classes, **HYDROLEINE** is invaluable, supplying as it does, the true brain-food, and being more easily assimilated by the digestive organs than any other emulsion.

The principles upon which this discovery is based have been described in a treatise on "The Digestion and Assimilation of Fats in the Human Body," and "Consumption and Wasting Diseases," by two distinguished London physicians, which will be sent free on application.

SOLD BY DRUGGISTS GENERALLY.

C. N. CRITTENTON,

SOLE AGENT FOR THE UNITED STATES. 115 FULTON STREET, N. Y.

A Sample of Hydroleine will be sent free upon application, to any physician (enclosing business card) in the U. S.

PRICE, $4.00.

ADDRESS PUBLISHER OF MEDICAL AND SURGICAL REPORTER, P. O. BOX 843, PHILADELPHIA.

WE ARE CONFIDENT THAT WE HAVE REACHED THE **Highest Degree of Perfection** *IN SOLVING THE* **INFANT FOOD PROBLEM.**

Lacto-Preparata.

A Prepared Human Milk perfectly Sterilized and especially designed for Children from birth to six or eight months of age.

Made wholly from cow's milk with the exception that the fat of the milk is partially replaced by cocoa butter. Cocoa butter is identical with milk fat in food value and digestibility, being deficient only in the principle which causes rancidity. The milk in *Lacto-Preparata* is treated with Extract of Pancreas at a temperature of 105 degrees, a sufficient length of time to render twenty-five per cent. of the casein soluble, and partially prepare the fat for assimilation. In this process the remaining portion of the casein not peptonized, is acted upon by the pancreatic ferment in such a manner as to destroy its tough tenacious character, so that it will coagulate in light and flocculent curds, like the casein in human milk.

Composition:

ALBUMINOIDS,	19 Parts.
MILK SUGAR,	64 "
FAT,	10 "
MINERAL MATTER,	3 "
CHLORIDE of SODIUM added,	½ "
PHOSPHATES of LIME added,	½ "
MOISTURE,	3 "

SEND FOR SAMPLE and compare it with every other food used in artificial feeding of Infants.

Lacto-Preparata is not designed to replace our **Soluble Food,** but is better adapted for Infants up to eight months of age.

Carnrick's Soluble Food

Is the Nearest Approach to Human Milk that has thus far been produced, with the exception of Lacto-Preparata.

During the past season a large number of Physicians and eminent Chemists visited our Laboratory at Goshen, N. Y., and witnessed every detail connected with the production of Carnrick's Soluble Food. This invitation to witness our process is continuously open to Physicians and Chemists. All expenses from New York to Goshen and return will be paid by us. The care used in gathering the milk, its sterilization, and the cleanliness exercised in every step, cannot be excelled. Soluble Food has been improved by increasing the quantity of milk sugar and partially replacing the milk fat with cocoa butter.

Phospho-Caffein Comp.

(GRANULAR EFFERVESCING.)

A SEDATIVE, NERVE AND BRAIN FOOD.

This preparation has been thoroughly tested, and found to produce the happiest effects in Headaches, Neuralgia, Sleeplessness, and General Nervous Irritability. We are confident that the above combination will be found superior to any of the various preparations that are used in nervous affections. It is not only a nerve sedative, but a Brain and Nerve Food. The depressing effects of the sedative ingredients are fully overcome by its reconstructive constituents.

As a harmless and positive remedy in Headaches and Insomnia, we are certain it has no equal It is far more palatable than any of the preparations used for similar purposes.

PUT UP IN FOUR, EIGHT, AND THIRTY-TWO OUNCE BOTTLES.

REED & CARNRICK, New York.

Champagne ANALYZED

Of Interest to all Medical Practitioners.

WHAT IS SAID BY

THOMAS KING CHAMBERS, M.D., F.R.C.P.
R. OGDEN DOREMUS, M.D.
F. W. PAVY, M.D., F.R.S.

"Champagne, with a minimum of alcohol, is by far the wholesomest, and possesses remarkable exhilarating power."—THOMAS KING CHAMBERS, M.D., F.R.C.P.

"Having occasion to investigate the question of wholesome beverages, I have made a chemical analysis of the most prominent brands of Champagne. I find G. H. Mumm & Co.'s Extra Dry to contain, in a marked degree, less alcohol than the others. I therefore most cordially commend it not only for its purity but as the most wholesome of the Champagnes."—R. OGDEN DOREMUS, M.D., *Professor of Chemistry, Bellevue Hospital Medical College, New York.*

"Champagne, while only possessing the alcoholic strength of natural wines, is useful for exciting the flagging powers in case of exhaustion."—F. W. PAVY, M.D., F.R.S., *Lecturer on Physiology at Guy's Hospital, London.*

The remarkable vintage of 1884 of **G. H. MUMM & CO.'S EXTRA DRY CHAMPAGNE,** the finest for a number of years, is now imported into this market, and pronounced by connoisseurs unsurpassed for excellence and bouquet.

THIRD EDITION.

ACCIDENTS AND EMERGENCIES

By CHARLES W. DULLES, M.D.

"A work that ought to be in every home, and every home that has a copy kept where it can be consulted at short notice is likely to find it worth many times its small cost."—*Philadelphia Evening Telegraph*, May 5, 1888.

"The methods of treatment recommended are trustworthy and reliable. The manual is one of the best of this class of books and should be in the library of every householder, ready for reference at a moment's notice."—*Science*, May 18, 1888.

Sent on receipt of 75 Cents.

ADDRESS:

Publisher **Medical and Surgical Reporter,**

P.O. Box 843. PHILADELPHIA, PA.

The utility of artificial legs and arms with rubber feet and hands is evidenced by the operations of over nine thousand men, women, and children distributed throughout the entire civilized world. Strange as it may seem, this army mingles with the vast populace and their misfortunes are lost to sight. Men engaged in all manner of vocations, manual, arduous, menial, on the farm, at the forge, in the mines, at the desk. Women attend to their household duties, whether in the kitchen, laundry, drawing-room, or parlor. Children wearing one or a pair of artificial limbs are no longer objects of pity and dependence; they indulge with other children in all manner of sports, they skate, ride the bicycle, romp and tumble about just as healthy and merry children should do.

One little fellow from Connecticut writes: "I can climb trees, play base-ball, and other out-door games as well as other 14-year-old boys."

A large illustrated book, containing 400 pages and over 200 illustrations, will be sent free to those needing artificial legs and arms, or to physicians and others interested.

This book gives instructions how to order and be fitted while the subject remains at home.

PRICE, $4.00.
ADDRESS PUBLISHER OF
MEDICAL AND SURGICAL REPORTER,
P. O. BOX 843, PHILADELPHIA.

Sulfonal-Bayer has been before the Medical Profession for some time, receiving its unqualified endorsement, but the use has been limited in many cases, owing to the hesitation of the practitioner in recommending so costly a remedy.

It is a matter of gratification to us to be able to announce a substantial reduction in price of

THE NEW HYPNOTIC

SULFONAL-BAYER,

which will enable physicians to freely prescribe it whenever indicated, and will bring it within the reach of all classes of patients.

So much has been written and published regarding Sulfonal that it does not here seem necessary to set forth at length its peculiar merits. We have already published two pamphlets on this subject, and the points will be found to be fully exhibited in the series of contributions contained in them. These pamphlets will be mailed to applicants.

Sulfonal was discovered by Prof. Eugen A. Baumann, of Freiburg University, and was first prepared by the Farbenfabriken vorm. Friedr. Bayer & Co., Elberfeld.

Sulfonal-Bayer is supplied by us in half-ounce and one-ounce vials.

We prepare 5-grain and 15-grain Tablets of Sulfonal-Bayer. The tablet form is admirably adapted to the purpose of administering this drug, as when they are placed in the liquids they disintegrate, and are thus received into the system.

We also put up Sulfonal-Bayer in the form of our Soluble Pills, containing 5 grains each.

ANALGESIC—ANTIPYRETIC

PHENACETINE-BAYER.

Phenacetine-Bayer (Para-Acetphenetidine) is a white, glossy, crystalline powder, perfectly tasteless, slightly soluble in water, a little more soluble in glycerine, but most freely in alcohol, and it was first prepared by the Farbenfabriken vorm. Friedr. Bayer & Co., Elberfeld.

Phenacetine-Bayer has been received with great favor by the Medical Profession, and is daily growing in esteem both as an Antipyretic and Analgesic.

Phenacetine-Bayer is an important antineuralgic; its effect is more energetic than that of Antipyrine, and does not cause lassitude or any other disagreeable symptoms.

Our two pamphlets on Phenacetine-Bayer, containing the valuable testimony of eminent physicians, will be mailed on application.

AND OF ALL DRUGGISTS.

NEURALGIAS PILLS OF DR. MOUSSETTE.

The **Moussette Pills** of aconitine and quinium, calm or cure *Gastralgia, Hemicrania, Headache, Sciatica*, and the most obstinate Neuralgias.

"The sedative action exerted by the **Moussette Pills** "upon the apparatus of the sanguineous circulation by the "intermediation of the vaso-motor nerves, indicates their "use in *neuralgias of the trigemini nerves*, (fifth pair), *con-* "*gestive neuralgias*, and *painful and inflammatory Rheumatismal* "*affections*."

"Aconitine produces marvelous effects in the treatment "of *facial neuralgias* when they are not symptomatic of "intracranial tumor."—*Society of Biology of Paris, Meeting* "*of the 28th February, 1880.*

DOSE—Take 3 to 6 pills during the twenty-four hours.

ACCEPT ONLY THE GENUINE MOUSSETTE PILLS OF

CLIN & CO.,—Paris.

GRAND NATIONAL PRIZE OF 16,600 FRANCS,

QUINA-LAROCHE

This meritorious **Elixir, QUINA-LAROCHE,** is prepared from the **three** Cinchonas; it is an agreeable and doubtless highly efficacious remedy.

—*The Lancet.*

VINOUS ELIXIR,

A STIMULATING RESTORATIVE

——AND——

ANTI-FEBRILE TONIC.

QUINA-LAROCHE under the form of a vinous **Elixir** contains the totality of the numerous principles of the **three** Cinchona barks. It is a preparation which renders great services to Therapeutics.—Extract of the *Gazette des Hôpitaux*, Paris.

FAR SUPERIOR TO ALL ORDINARY CINCHONA WINES.

LAROCHE'S QUINA, tried by the Academy of Medicine of Paris, is a specially prepared COMPOUND EXTRACT of Quinquina, a careful analysis, confirmed by experience, has shown that most of the wines and syrups hitherto used have not contained all the properties of this precious bark, of these some, although beneficial, are altogether lost, while many preparations contain but half the properties of the bark in varying proportions.

MR. LAROCHE, by his peculiar method, has succeeded in extracting all the active principles of the quinquina, combining these with *Catalan Wine* forming an Elixir free from the disagreeable bitterness of other similar preparations. Practitioners have found triple advantages in the use of this Elixir, it is a *strong tonic*, is easily administered, and perfectly harmless, being free from the unpleasant effects of Quinine.

THE FERRUGINOUS QUINA-LAROCHE is the invigorating tonic *par excellence*, having the advantage of being easily assimilated by the gastric juice; without, in any way, deranging the action of the digestive organs, proving itself to be a most efficacious remedy in cases of impoverishment of the blood, ANÆMIA, CHLOROSIS, INTESTINAL HÆMORRHAGE, CASTRALGIA, EXHAUSTION, ETC., ETC.

PAPINE

THE ANODYNE.

Papine is the Anodyne or pain-relieving principle of Opium, the Narcotic and Convulsive Elements being eliminated. It has less tendency to cause Nausea, Vomiting, Constipation, Etc.

INDICATIONS.—

Same as Opium or Morphia.

DOSE.—

(ONE FLUID DRACHM)—represents the Anodyne principle of one-eighth grain of Morphia.

IODIA

The Alterative and Uterine Tonic.

FORMULA.—

Iodia is a combination of active principles obtained from the Green Roots of Stillingia, Helonias, Saxifraga, Menispermum, and Aromatics. Each fluid drachm also contains five grains Iod. Potas., and three grains Phos. Iron.

DOSE.—

One or two fluid drachms (more or less as indicated) three times a day before meals.

INDICATIONS.—

Syphilitic, Scrofulous and Cutaneous Diseases, Dysmenorrhea, Menorrhagia, Leucorrhea, Amenorrhea, Impaired Vitality, Habitual Abortions, and General Uterine Debility.

THE SUSTAINED SUPREMACY

OF

Fairchild's Pepsin,

In ACTIVITY, PERMANENCE and GENERAL EXCELLENCE

Has won for this product a wide use and recognition in all the principal markets of the world.

We guarantee it to be unchangeable, to maintain its activity and quality under all ordinary commercial conditions; it is therefore, by far the most available for the dispensing counter, as well as in the manufacture of every form of pepsin preparation.

Under exactly parallel conditions, with any proper percentage of acidity and with any proportion of such acidulated water to the albumen, Fairchild's pepsin is positively superior to any pepsin known.

It will, under absolutely comparative conditions, grain for grain, digest more albumen than any other pepsin made.

We will be pleased to send samples to any physician who may wish to ascertain for himself the relative activity of Fairchild's pepsin, or to submit it to any practical trial.

Prices and complete information upon application.

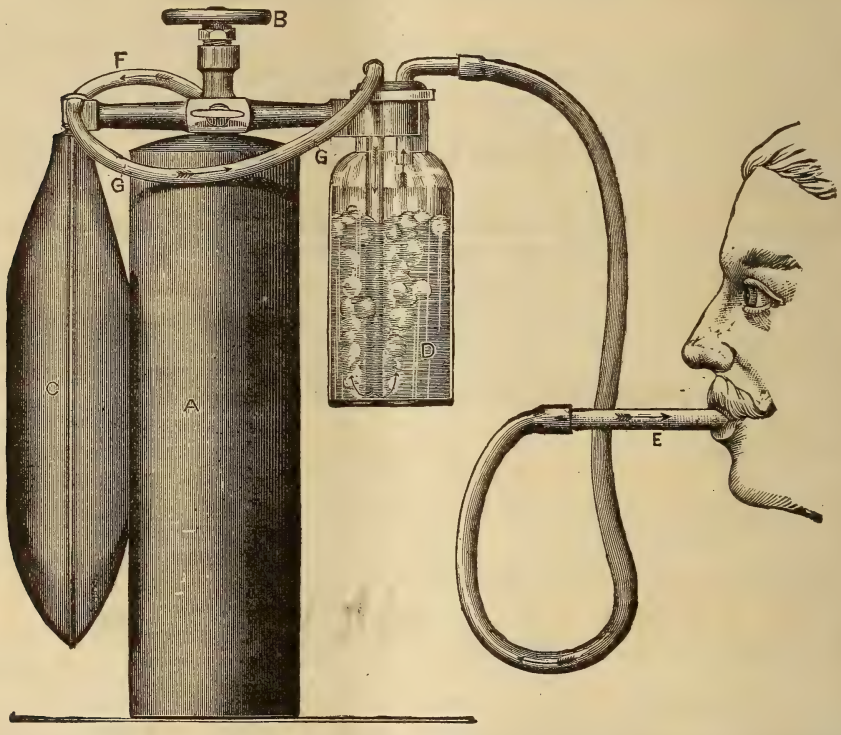
INHALATION APPARATUS

FOR

THE THERAPEUTIC ADMINISTRATION OF OXYGEN.



In the treatment of lung troubles by Oxygen its exhibition by inhalation is preferred. The apparatus herewith shown is a modification of the Nitrous Oxide apparatus which we have supplied for many years. It is made in the best manner throughout, and is the outcome of years of experience in the manufacture of gas apparatus. It will be found to meet all the requirements.

We supply the gas in two sizes of cylinders, containing respectively forty and one hundred gallons, either pure Oxygen, or a mixture of Oxygen and Nitrous Oxide in definite proportions of 20 per cent., and forty per cent. of Nitrous Oxide.

Whether pure or mixed the gas is sold at the uniform price of 5 cents a gallon. The cost of the cylinders will be refunded on their return empty with the valves in good condition. Full description of Inhalation and Enema apparatuses with directions for use accompany each apparatus, or will be supplied on application.

PRICES.

Inhalation Apparatus	$5.00
Cylinder, 40 gallons' capacity	6.00
40 gallons Gas, either pure Oxygen or mixed Oxygen and Nitrous Oxide	2.00
Complete Apparatus, Cylinder, and 40 gallons Gas	$13.00
Inhalation Apparatus	$5.00
Cylinder, 100 gallons' capacity	15.00
100 gallons Gas, either pure or mixed	5.00
Complete Apparatus, Cylinder, and 100 gallons Gas	$25.00

THE BEST ANTISEPTIC
FOR BOTH INTERNAL AND EXTERNAL USE.

ANTISEPTIC, PROPHYLACTIC, DEODORANT.

LISTERINE

NON-TOXIC, NON-IRRITANT, NON-ESCHAROTIC.

FORMULA—Listerine is the essential antiseptic constituent of Thyme, Eucalyptus, Baptisia, Gaultheria and Mentha Arvensis, in combination. Each fluid drachm also contains two grains of refined and purified Benzo-boracic Acid.

DOSE—Internally: One teaspoonful three or more times a day (as indicated) either full strength, or diluted, as necessary for varied conditions.

LISTERINE is a well-proven antiseptic agent—an antizymotic—especially adapted to internal use, and to make and maintain surgical cleanliness—asepsis—in the treatment of all parts of the human body, whether by spray, irrigation, atomization, or simple local application, and therefore characterized by its particular adaptability to the field of

PREVENTIVE MEDICINE—INDIVIDUAL PROPHYLAXIS.

Diseases of the Uric Acid Diathesis.

LAMBERT'S

LITHIATED HYDRANGEA

KIDNEY ALTERATIVE—ANTI-LITHIC.

FORMULA—Each fluid drachm of "Lithiated Hydrangea" represents thirty grains of FRESH HYDRANGEA and three grains of CHEMICALLY PURE Benzo-Salicylate of Lithia. Prepared by our improved process of osmosis, it is INVARIABLY of DEFINITE and UNIFORM therapeutic strength, and hence can be depended upon in clinical practice.

DOSE—One or two teaspoonfuls four times a day (preferably between meals).

Urinary Calculus, Gout, Rheumatism, Bright's Disease, Diabetes, Cystitis, Hæmaturia Albuminuria, and Vesical irritations generally.

We have much valuable literature upon { GENERAL ANTISEPTIC TREATMENT, LITHEMIA, DIABETES, CYSTITIS, ETC. } To forward to Physicians upon request.

21 PARK PLACE N.Y.

Geo Hamlin Prest. Chas Roome Parmele Treas.

GENTLEMEN:

The Case of your wines sent me for analysis by Dr. A. L. Hummel, of the "Annals of Hygiene," containing specimens of your La Rosa Zinfandel, Mataro, Riesling, Royal Tokay, and Royal Grape Brandy, has been duly received.

I have examined them for the common contaminants of wine; to wit: Sulphurous acid and sulphites, salicylic acid, fuchsin, lead salts, etc., none of which I found present therein.

I have also determined their alcoholic strength, extractives, and ashes, and found them to correspond strictly in this respect with the standard of pure and natural wines, which cannot be said of many of the imported wines.

As a native of a wine-producing country, I consider myself somewhat of a judge of wines, and regard your products as comparing more than favorably with most of the wines from abroad which are sold at higher prices, so much so that I enclose within my order for fifty bottles of La Rosa Zinfandel, which I expect to use hereafter exclusively at my table.

Very Respectfully,

L. WOLFF, M.D.,
Demonstrator of Chemistry, Jefferson Medical College.

NEW AND RELIABLE RECIPES FOR PHYSICIANS PRESCRIBING.

In order to get the full therapeutic effects, physicians will please specify (WARNER & CO.) when ordering or prescribing.

☞The coating of the following pill will dissolve in 4½ minutes.☜

PIL: CHALYBEATE COMP.

(WARNER & CO.)

Nux Vomica is added as an ingredient to Pill Chalybeate to increase the tonic effect when desired.

Composition of each Pill.—℞ (Chalybeate Mass.), Carb. Protoxide of Iron, gr. 2½., Ext. Nuc. Vom. gr. 1-6.

DOSE—1 to 3 Pills.

Most advantageously employed in the treatment of Anæmia, Chlorosis, Phthisis, Scrofula, Loss of Appetite, etc.

PIL: ANTISEPTIC.

Each Pill contains: Sulphite Soda, 1 gr. Salicylic Acid, 1 gr. Ext. Nuc. Vomica, ¼ gr.

DOSE—1 to 3 Pills.

Pil. Antiseptic is prescribed with great advantage in cases of Dyspepsia attended with acid stomach and enfeebled digestion following excessive indulgence in eating or drinking. It is used with advantage in Rheumatism.

Prepared by WM. R. WARNER & CO.

PIL: ANTISEPTIC COMP.

(WARNER & CO.)

Each Pill contains: Sulphite Soda, 1 gr. Salicylic Acid. 1 gr. Ext. Nuc. Vomica, ⅛ gr. Powd. Capsicum, 1-10 gr. Conc't Pepsin, 1 gr.

DOSE—1 to 3 Pills.

Pil. Antiseptic Comp. are prescribed with great advantage in cases of Dyspepsia, Indigestion, and Malassimilation of Food.

Supplied upon physician's prescription by all leading druggists.

1228 MARKET ST., Phila. 18 LIBERTY ST., New York.

Intestinal Diseases of Children.

"In Cholera Infantum," says Dr. Louis Starr, "the irritability of the stomach is a formidable barrier to alimentation; nevertheless, every effort must be made to give food in small quantities and at short intervals." Clinical experience, the only conclusive test, has proved the great efficacy in this disease, of MELLIN'S FOOD dissolved in water only and given cold, in small amount frequently repeated. "In MELLIN'S FOOD," says Dr. Eustace Smith, "the whole of the starch is converted into dextrine and grape sugar (properly maltose) so that the greater part of the work of digestion is performed before the food reaches the child's stomach." He also says, "I have never seen any signs of fermentation which I could attribute to the influence of maltose." As it is non-fermentable and so quickly assimilated, MELLIN'S FOOD is the best food for infants suffering from this complaint until convalescence has been sufficiently established to allow the regular diet to be resumed.

A sample of MELLIN'S FOOD will be sent to any physician, free of all expense, upon application.

THE VALUE OF NUTRITION IN DISEASE.

All physicians who have ever used Murdock's Liquid Food and Suppositories recognize their value over all other foods, in breaking up disease and building up the patients after disease, preventing a relapse, **as the same results are obtained as in surgery.** Its value in surgical cases we illustrate by the records of the different cities and of Murdock's Free Surgical Hospital for Women, which is the largest in the United States. It contains 114 beds, every bed free, including operation, the operations ranging from 1000 to 1200 yearly, representing 90 of the worst classes known in surgery. Among these cases we have had **Cancer of uterus** (*Kolpo-hysterectomy*), 13; **Salpingitis** (*Tait's operation*), 31; **Fibroid of uterus** (*abdominal hysterectomy*), 19; **Ventral operation, hernia,** (*abdominal section*), 12; **Cancer of bowel** (*incision*), 2; **Parovarian cyst, 6; Papillomatous cyst** (*extirpation*), 4; **Tubercular peritonitis** (*incision*), 1, **Ovarian cystoma 27; Nymphomania** (*Battey*), 1; **Exploratory abdominal incisions, 12; Fibroid with abdominal abscess** (*Hegar*), 2; **Hysterorraphy, 2; Dermoid cyst, 3; Cirrhotic ovaries,** (*Battey*), 4; **Fibroid uterus** (*Hegar*), 6; **Hystero-epilepsy** (*Battey*), 1; **Haemato-Salpinx** (*Tait*), 5; **Rupture of intestine into vagina, 1; Dislocated kidney, 2; Fibroid tumor abdominal wall, 1; Resection of intestine** (*Senn*), 1; **Ruptured perineum, 294.** Patients are in the Hospital 8 days before and 26 days after operation, on an average.

In Boston, last year, 42 deaths were from Cancer in the Breast. In Murdock's Hospital, 35 such cases were operated on without a death, the patients remaining in the Hospital, on an average, 18 days.

Mortality in Boston,	. . . . .	25.60	per 1000.
"	of Women in Boston, ...	29,00	" "
"	in **Murdock's Free Surgical Hospital,** .	**5.00**	" "
"	New York, ...	26.32	" "
"	Philadelphia, ...	20.00	" "
"	Chicago, ...	20.90	" "
"	St. Louis, ...	20.49	" "

showing our mortality is only one-sixth as great as of those in health. As good results were obtained in our General Hospital, which we kept open 27 months, **thus showing the value of nutrition as found in Murdock's Liquid Food, and so recognized by the British and American Medical Associations,** before which essays were read and discussed, and it is the only Raw food preparation on which essays were ever read.

Physicians are invited to visit our Hospitals and Works, also to send in patients and to be present at the operations. For any physician who has not used our Liquid Food (and Suppositories for adults and infants), we will deliver free samples to any express company in Boston.

When babies do not thrive, never change their food, but add five or more drops at each feeding of Murdock's Liquid Food, and their lost or needed vitality will be restored in less than thirty days. It is invaluable when weaning babies or when teething. If mothers will take one teaspoonful to a tablespoonful before each meal and on retiring, they will receive as much benefit as the baby.

Murdock Liquid Food Co., Boston.

ALETRIS CORDIAL

UTERINE TONIC AND RESTORATIVE.

Prepared from the Aletris Farinosa or True Unicorn and Aromatics.

INDICATIONS.

Amenorrhea, Dysmenorrhea, Leucorrhea, Prolapsus Uteri, Sterility, to Prevent Miscarriage, Etc.

DOSE:—ONE TEASPOONFUL THREE OR FOUR TIMES A DAY.

UNRIVALED AS A UTERINE TONIC IN IRREGULAR, PAINFUL, SUPPRESSED AND EXCESSIVE MENSTRUATION.

It Restores Normal Action to the Uterus, and Imparts Vigor to the Entire Uterine System.

☞Where women have miscarried during previous pregnancies, or in any case where miscarriage is feared, the ALETRIS CORDIAL is indicated, and should be continuously administered during entire gestation.

CHAS. CLAY, M. R. C. S., Manor House, Dewsbury, England, says:—I find Aletris Cordial (Rio) is of great service in threatened miscarriage.

FRANCIS E. CANE, L. R. C. S., &c., Leeds, England, says:—I have tried the Aletris Cordial (Rio) in two cases of long standing dysmenorrhea, with excellent results. One of these patients has spent a week in bed every month for two years. After all the usual remedies, I put her on Aletris Cordial, and for the last two periods she has been out and about all the time.

L. M. WATSON, M. D., Delhi, Ills., says:—I have used Aletris Cordial (Rio) in cases of dysmenorrhea, suppressed menses and threatened miscarriage, and also, combined with Celerina, as a tonic after confinement, with the happiest results, and now I am using it on a case of leucorrhea, with injections of S. H. Kennedy's Extract of Pinus Canadensis, and it is acting like a charm.

P. H. OWEN, M. D., Morganville, Ala., says:—I have prescribed Aletris Cordial (Rio) in several cases with the most satisfactory results, and regard it as the best uterine tonic I have met with in a professional experience of over twenty-five years. In cases of threatened miscarriage it acts like a charm. Would recommend its continuous administration in all cases when there is any indication of miscarriage.

Dr. W. BERTHELOT, Santander, Spain, says:—I have tried the Aletris Cordial (Rio), and it has seemed to me to be useful, especially in cases of dysmenorrhea.

Dr. RASQUINET, Jupile, near Liege, Belgium, says:—I tried Aletris Cordial (Rio) in the case of a woman who had had several miscarriages at the end of five months, and who is now again pregnant, having reached the seventh month: thanks to Aletris Cordial.

R. REECE, M. R. C. S., Walton-on-Thames, England, says:—Aletris Cordial (Rio) in painful menstruation is most valuable. A wife of a minister suffered much, and had had three miscarriages. I prescribed Aletris Cordial. She has for the first time, gone her full time, and was safely confined with a male child.

J. T. COLLIER, M. D., Brooks, Me., says:—I have used your Aletris Cordial (Rio) in cases of females at the menopause. Consider it one of the finest remedies for these cases.

Dr. GORDILLON, St. Amand, France, says: I have tried the Aletris Cordial (Rio) in a case of dysmenorrhea. The result I obtained from the use of your preparation was excellent, better than I had obtained in the same patient by prescribing the usual remedies employed in such cases.

W. F. TOOMBS, M. D., Morrillton, Ark., says:—I have used a great deal of your Aletris Cordial (Rio) and I find it all you claim for it in amenorrhea, dysmenorrhea, metritis, leucorrhea; I don't think it has an equal. I have used it in two cases of threatened miscarriage and the trouble was obviated. For a general Uterine Tonic I know of nothing superior.

R. D. PATTERSON, L. R. C. S. &c., Medical Officer, Caledon Dispensary, Co. Tyrone, Ireland, says:—I have very great pleasure in testifying to the very high opinion I hold of Aletris Cordial (Rio) in threatened miscarriage.

SPORTING AND ATHLETIC GOODS OF EVERY DESCRIPTION.

No Chemicals.

W. BAKER & CO.'S Breakfast Cocoa

Is Absolutely Pure, and it is Soluble.

To increase the solubility of the powdered cocoa, various expedients are employed, most of them being based upon the action of some alkali, potash, soda or even ammonia. Cocoa which has been prepared by one of these chemical processes, can usually be recognized at once by the distinct alkaline reaction of the infusion in water.

W. Baker & Co.'s Breakfast Cocoa

is manufactured from the first stage to the last by perfect mechanical processes, **no chemical being used in its preparation.** By one of the most ingenious of these mechanical processes the greatest degree of fineness is secured without the sacrifice of the attractive and beautiful red color which is characteristic of an absolutely pure and natural cocoa.

BOUDAULT'S PEPSINE

The only Pepsine used in the Hospitals of Paris for the last Thirty Years.

Unlike the various substitutes which, in most cases, are but unscientific or incompatible compounds, forced upon the Medical Profession as aids to digestion by extensive advertising, but which, when submitted to the proper tests, are found to be useless as digestive agents, Pepsine is constantly gaining in the esteem of the careful practitioner.

Since the introduction of Pepsine by Boudault and Corvisart in 1854, the original BOUDAULT'S PEPSINE HAS BEEN AT ALL TIMES CONSIDERED THE BEST, as is attested by the awards it has received at the Expositions of 1867, 1868, 1873, in 1876 at the Centennial Exposition of Philadelphia, and in 1878 at the Paris Exposition.

The most reliable tests, carefully applied, will satisfy everyone that BOUDAULT'S PEPSINE HAS A MUCH HIGHER DIGESTIVE POWER than the best Pepsines now before the Profession, and is therefore especially worthy of their attention.

BOUDAULT'S PEPSINE is prepared in the form of Pepsine Acid and Pepsine Neutral. It is sold in bottles of one ounce, with a measure containing exactly five grains; also in bottles of four, eight, and sixteen ounces for dispensing.

BOUDAULT'S WINE OF PEPSINE

FORMULA OF DR. CORVISART.

The taste of Pepsine being perfectly disguised in this Wine, it may be recommended to persons who have difficulty in taking Pepsine in the form of Powder. This Wine is tested so that a tablespoonful of it is equal in digestive power to ten grains of Boudault's Pepsine in powder. Sold only in bottles of eight ounces.

TANRET'S PELLETIERINE

For the Treatment of Tape-Worm (Tænia Solium).

This New Tænifuge, the Active Alkaloid of Pomegranate Bark, has of late come into extensive use in France for the treatment of Tape-Worm (Tænia Solium). The results of numerous experiments with it at the Marine Hospitals of Toulon, St. Mandrier, etc., and in the Hospitals of Paris, St. Antoine, La Charité, Necker Beaujon, etc., have all been most satisfactory. Doctor Dujardin Beaumetz, Member of the Academy of Medicine, and Professor Laboulbene, in their report to the Society of Therapeutics, have given it their unqualified approval, after the most searching experiments. This preparation is pleasant to administer, and, if certain preliminaries are observed, success will be insured.

Sold only in bottles containing one dose.

DUCRO'S ALIMENTARY ELIXIR

A Combination uniting the properties of Alcoholic Stimulants and Raw Meat.

This preparation, which has been used with great success in the hospitals of Paris since 1868, is adapted to the treatment of all diseases requiring administration, in a small volume, of a tonic able to stimulate and support the vital forces, as *Pulmonar Phthisis, Depression and Nervous Debility, Adynamia, Malarious Cachexia, etc.*

Prepared by EMILE DURIEZ & CO., Successors to DUCRO & CIE, Paris.

KIRKWOOD'S INHALER

This is the only complete, reliable, and effective inhaler in use, arranged for the direct application of Muriate of Ammonia and other remedial agents in the state of vapor to the diseased parts of the air-passages in the treatment of catarrh and diseases of the throat and lungs. No heat or warm liquids required in its use.

It is entirely different from the various frail, cheap instruments that have been introduced.

KIRKWOOD'S INHALER is accompanied by testimonials of the highest professional character, together with carefully prepared formulas for use.

RETAIL PRICE, COMPLETE, $2.50.

☞ A liberal discount allowed to the trade and profession. For descriptive pamphlet or other information address

I. EDMONSON ATKINSON, M.D., Professor of Materia Medica and Therapeutics, Clinical Medicine and Dermatology.
R. DORSEY COALE, PH.D., Professor of Chemistry and Toxicology.
JOHN NOLAND MACKENZIE, M.D., Clinical Professor of Diseases of the Throat and Nose.
HERBERT HARLAN, M.D., Demonstrator of Anatomy.

For catalogue and further information, address: **Dr. J. EDWIN MICHAEL, Dean, 937 Madison Avenue.**

DENTAL DEPARTMENT.

Eighth Annual Announcement. Next regular session begins October 1st, 1889. New and excellent Infirmary and Laboratory, with abundance of clinical material.

FACULTY:

FRED. J. S. GORGAS, M.D., D.D.S., Professor of Principles of Dental Science, Dental Surgery, and Dental Mechanism.
JAMES H. HARRIS, M.D., D.D.S., Professor of Operative and Clinical Dentistry.
I. EDMONSON ATKINSON, M.D., Professor of Materia Medica and Therapeutics.
FRANCIS T. MILES, M.D., Professor of Physiology.
L. McLANE TIFFANY, M.D., Clinical Professor of Oral Surgery.
J. EDWIN MICHAEL, M.D., Professor of Anatomy.
R. DORSEY COALE, PH.D., Professor of Chemistry.
JOHN C. UHLER, M.D., D.D.S., Demonstrator of Mechanical Dentistry.
CHAS. L. STEEL, M.D., D.D.S., Demonstrator of Operative Dentistry.
HERBERT HARLAN, M.D., Demonstrator of Anatomy.
AND EIGHT ASSISTANT DEMONSTRATORS.

For catalogue and other information, apply to **Dr. F. J. S. GORGAS, Dean, 845 Eutaw Street, Baltimore.**

Medico-Chirurgical College of Philadelphia.

JAS. E. GARRETSON, A.M., M.D., Professor of Oral and Clinical Surgery.
WM. H. PANCOAST, A.M., M.D., Professor of General, Descriptive, and Surgical Anatomy and Clinical Surgery.
GEO. E. STUBBS, A.M., M.D., Professor of Clinical Surgery.
WM. F. WAUGH, A.M., M.D., Professor of Principles and Practice of Medicine and of Clinical Medicine.
ABRAHAM S. GERHARD, A.M., M.D., Professor of Forensic and Clinical Medicine.
WM. S. STEWART, A.M., M.D., Professor of Obstetrics and Clinical Gynecology.
H. EARNEST GOODMAN, M.D., Professor of Principles and Practice of Surgery and Clinical Surgery.
P. D. KEYSER, A.M., M.D., Dean, Professor of Ophthalmology.
SAMUEL B. HOWELL, A.M., M.D., Professor of Chemistry.
JOHN V. SHOEMAKER, A.M., M.D., Professor of Materia Medica, Pharmacology, Therapeutics and Clinical Medicine.
E. E. MONTGOMERY, B.S., M.D., Professor of Gynecology.
JAS. M. ANDERS, Ph.D., M.D., Professor of Hygiene and Clinical Diseases of Children; Associate Professor of Physiology
JOHN V. SHOEMAKER, A.M., M.D., Clinical Professor Skin Diseases.
FRANK WOODBURY, A.M., M.D., Honorary Professor of Clinical Medicine.
WM. B. ATKINSON, A.M., M D. Honorary Professor of Sanitary Science and Paediatrics.

The Regular Session begins September 30th, 1889, and continues until the middle of April. It is preceded by a Preliminary Session of three weeks, and followed by a Spring Session lasting until the middle of June.

Seats are issued in the order of matriculation, and are forfeitable if fees are not paid before November 1st.

Preliminary examination or equivalent degree, and a three years' graded course obligatory. A fourth year voluntary.

Instruction is given by lectures, clinical teaching and practical demonstrations. In the subjects of Anatomy, Pharmacy, Chemistry, Histology and Pathology the usual methods of instruction are largely supplemented by laboratory work.

Examinations are held at the close of each Regular Session upon the studies of the term. Although the degree of Doctor of Medicine is conferred at the end of the third year, a fourth year is earnestly recommended, at the end of which the degree of Doctor of Medicine *cum laude* is given.

FEES.

Matriculation, $5: first and second years, each, $100; third year (no graduation fee), $100; fourth year, free to those who have attended three sessions in this school, to all others, $100.

Extra charges only for material used in the laboratories and dissecting-room.

For further information or announcement, address,

E. E. MONTGOMERY, M.D., Secretary,
Medico-Chirurgical College,
Cherry, below 18th Street, Philadelphia, Penna.

Medical College of Ohio.

Medical Department of the University of Cincinnati.

The Seventy-first Annual Session will begin September 4, 1889, and continue until March 1, 1890.

FEES.—Matriculation Ticket, $5.00; General Lecture Ticket, $75.00; Hospital Ticket, $5.00; Graduation Fee, $25.00.

For circulars, and further information, address

JAMES G. HYNDMAN, M.D., Secretary,
22 West Ninth Street, Cincinnati, Ohio.

WESTERN PENNSYLVANIA MEDICAL COLLEGE

CITY OF PITTSBURGH.

SESSIONS OF 1889—90.

The REGULAR SESSION begins on the last Tuesday of September, and continues six months. During this session, in addition to four Didactic Lectures, two or three hours are daily allotted to Clinical Instruction. Attendance upon two regular courses of lectures is requisite for graduation. A three years' graded course is also provided. The SPRING SESSION embraces recitations, clinical lectures and exercises, and didactic lectures on special subjects; this session begins the second Tuesday in April, and continues ten weeks.

The laboratories are open during the collegiate year for instruction in chemistry, microscopy, practical demonstrations in medical and surgical pathology, and lessons in normal histology. Special importance attaches to "the superior clinical advantages possessed by this College." For particulars, see annual announcement and catalogue, for which, address the Secretary of Faculty, Prof. J. W. J. McKENNAN.

Business correspondence should be addressed to
PROF. W. J. ASDALE, 2107 Penn Avenue, Pittsburgh.

Woman's Medical College
OF BALTIMORE.

S. E. Cor. Druid Hill Ave. and Hoffman St., Baltimore, Md.

THE EIGHTH ANNUAL SESSION WILL BEGIN ON WEDNESDAY, OCTOBER 2d, 1889.

For further information or catalogue, address
RANDOLPH WINSLOW, M.D., Acting Dean,
No. 1, Mount Royal Terrace, Baltimore, Md.

Medical Department, State University of Iowa,
at Iowa City, Iowa.

The next Session will begin on September 11, 1889, and continue until March 12, 1890. Attendance upon three courses of lectures, of six months each, is requisite to graduation. The facilities for dissection and clinical study are unsurpassed.

TERM EXPENSES—Lecture Ticket, $20.00; Demonstrator's Ticket, $10.00; Matriculation Ticket, $5.00 (paid but once); Hospital Ticket, $3.00; Examination Fee (for final examination) $25.00. No charge for dissecting material. For further information, address DR. A. C. PETERS, Ast. Sec'y, Iowa City, Iowa.

College of Physicians and Surgeons
of Baltimore, Md.

The Preliminary Course will begin September 15th, 1889. The Regular Session will open October 1st, 1889, and close about March 15th, 1890.

For catalogue containing full information, address
THOMAS OPIE, M. D., Dean,
N. W. Cor. Calvert and Saratoga Sts., Baltimore, Md.

DISEASES OF THE EYE.

Systematic and Practical Instruction at the Philadelphia Polyclinic, including daily use of the Ophthalmoscope and test lenses. Special course in Ophthalmology begins September 30th.

For particulars, address

EDWARD JACKSON, M. D.,
215 South Seventeenth St., Philadelphia.

DETROIT COLLEGE OF MEDICINE.

SESSION 1889-90.

Clinical and Practical teaching are made an important feature of this College. Clinical instruction is given daily at HARPER, ST. MARY'S and ST. LUKE'S HOSPITAL, at the COLLEGE, at COLLEGE EYE and EAR INFIRMARY, ST. MARY'S FREE EYE and EAR INFIRMARY, and at the three FREE DISPENSARIES. The facilities offered by this college are unsurpassed for the practical study of MEDICINE, SURGERY, OBSTETRICS, GYNÆCOLOGY, DISEASES OF CHILDREN, GENITO-URINARY, and ORTHOPÆDIC SURGERY, OPHTHALMOLOGY and OTOLOGY, DERMATOLOGY and LARYNGOLOGY.

REGULAR SESSION opens on Wednesday, Sept. 25, and continues six months. During the session, the Professors will take special pains to examine the Students upon the subjects of the previous lectures.

SPRING SESSION begins April 2d, 1890; and closes June 11th.

FEES.—Matriculation fee, $5; Fees for Regular Session, $50; Spring Session, $10, to those who attend the regular term—to all others, $25; Hospital Fee, $10; Graduation Fee, $30; Perpetual Ticket, $100.

For further particulars, and for College Circular, apply to

H. O. WALKER, M.D., Secretary,
33 Lafayette Ave., Detroit, Mich.

UNIVERSITY OF PENNSYLVANIA.—Medical Department.

The 124TH ANNUAL WINTER SESSION will begin Tuesday, October 1st, 1889, at 12 M., and continue until May 1st, 1890.
The PRELIMINARY SESSION begins September 18th, 1889.

The curriculum is graded and three annual winter sessions are required. Practical instruction, including laboratory work in Chemistry, Histology, Osteology and Pathology, with Bedside Instruction in Medicine, Surgery and Gynecology are a part of the regular course and without additional expense.

FACULTY.

JOSEPH LEIDY, M.D., LL.D., Professor of Anatomy.
D. HAYES AGNEW, M.D., LL.D., Honorary Professor of Clinical Surgery.
WILLIAM PEPPER, M.D., LL.D., Professor of Theory and Practice of Medicine, and of Clinical Medicine.
WILLIAM GOODELL, M.D., Professor of Gynecology.
JAMES TYSON, M.D., Professor of Clinical Medicine.
HORATIO C. WOOD, M.D., LL.D., Professor of Materia Medica, Pharmacy and General Therapeutics.
THEODORE G. WORMLEY, M.D., LL.D., Professor of Chemistry and Toxicology.
JOHN ASHHURST, JR., M.D., Professor of Surgery and of Clinical Surgery.
EDWARD T. REICHERT, M.D., Professor of Physiology.
WILLIAM F. NORRIS, M.D., Honorary Prof. of Ophthalmology
BARTON COOKE HIRST, M.D., Professor of Obstetrics.
J. WILLIAM WHITE, M.D., Professor of Clinical Surgery.
JOHN GUITÉRAS M.D., Professor of General Pathology and Morbid Anatomy.
GEORGE A. PIERSOL, M.D., Professor of Histology and Embryology.
SAMUEL G. DIXON, M.D., Professor of Hygiene.

For Catalogue and announcement containing particulars, apply to

DR. JAMES TYSON, Dean,
36th and Woodland Avenue, Philadelphia.

NATIONAL MEDICAL COLLEGE.

MEDICAL DEPARTMENT OF THE

COLUMBIAN UNIVERSITY,

WASHINGTON, D. C.

The 68th Annual Session will begin October 7th and end March 1st. Graded three years' course required. Women admitted. Professors: J. F. Thompson, W. W. Johnston, A. F. A. King, E. T. Fristoe, Wm. Lee, D. W. Prentiss, D. K. Shute.

For circulars, address

A. F. A. KING, M. D., DEAN, 726 THIRTEENTH ST., N. W., WASHINGTON, D. C.

ELIXIR COCA AND CALISAYA

(S. & O.)

A valuable nerve stimulant and tonic, entirely different from any other preparation of Coca or Calisaya. Made by a process which brings out in the highest degree the active principles of fresh

COCA LEAVES AND CINCHONA BARK.

Free from bitter taste or depressing effects after using. It is recommended to physicians as useful in Atonic Indigestion, Insomnia, Nervous Exhaustion, Mental Depression, etc.

Made only by

Walnut and 13th Streets, Philadelphia.

PHYSICIANS' OFFICE AND OPERATING

COATS.

MADE OF BLEACHED DRILLING;
WILL NOT SHRINK IN WASHING.

$1.25 each; $7.00 per ½ Dozen.

Single Coats by Post, 15 cents additional.

HIRSH, FRANK & CO.,

31 North Third St., Philadelphia.

☞In ordering, send chest measure and length of sleeve from middle of back.

BUFFALO LITHIA WATER

IN THE

Uric Acid Diathesis, Bright's Disease of the Kidneys, Chronic Inflammation of the Bladder, &c.

Dr. THOMAS H. BUCKLER, of Paris (formerly of Baltimore), SUGGESTER OF LITHIA as a Solvent for URIC ACID.

"Nothing I could say would add to the **WELL-KNOWN REPUTATION OF THE BUFFALO LITHIA WATER. I HAVE FREQUENTLY USED IT WITH GOOD RESULTS IN URIC ACID DIATHESIS, RHEUMATISM AND GOUT,** and with this object I have ordered it to Europe from Coleman & Rogers, of Baltimore. Lithia is in no form so valuable as where it exists in the Carbonate (the form in which it is found in the **BUFFALO LITHIA WATER**), Nature's mode of solution and division in water which has passed through Lepedolite and Spondumine Mineral formation."

Dr. WM. A. HAMMOND, of New York, Surgeon-General U. S. Army (Retired), Professor of Diseases of the Mind and Nervous System in the University of New York, &c.

"I have for some time made use of the Buffalo Lithia Water in cases of affections of the **NERVOUS SYSTEM,** complicated with **BRIGHT'S DISEASE OF THE KIDNEYS** or with a **GOUTY DIATHESIS.** The results have been eminently satisfactory. Lithia has for many years been a favorite remedy with me in like cases, but the **BUFFALO WATER CERTAINLY ACTS BETTER THAN ANY EXTEMPORANEOUS SOLUTION OF THE LITHIA SALTS,** and is, moreover, better borne by the Stomach. I also often prescribe it in those cases of **CEREBRAL HYPERÆMIA** resulting from over-mental work—in which the condition called **NERVOUS DYSPEPSIA EXISTS**—and generally with marked benefit."

HUNTER McGUIRE, M.D., LL.D., Late Professor of Surgery, Medical College of Virginia, Richmond.

"**BUFFALO LITHIA WATER,** *Spring No. 2,* as an **ALKALINE DIURETIC,** *is invaluable.* In **URIC ACID GRAVEL,** *and, indeed,* in *diseases generally dependent* upon a **URIC ACID DIATHESIS,** *it is a remedy of extraordinary potency.* I have prescribed it in cases of **RHEUMATIC GOUT,** *which had resisted the ordinary remedies, with wonderful good results.* I have *used it also in my own case, being a great sufferer from this malady, and have derived more benefit from it than from any other remedy.*"

Dr. ROBERT BATTEY, of Georgia, SUGGESTER OF BATTEY'S OPERATION.

"I would state that I have been using the Buffalo Lithia Water, No. 2, in my practice for three years past, in cases of **CHRONIC INFLAMMATION** of the **BLADDER,** whether induced by **STONE,** by enlarged **PROSTATE** in the aged, or by **NEGLECTED GONORRHŒA, AND HAVE SECURED EXCELLENT RESULTS,** which encourages me to prescribe it for the future."

Dr. CYRUS EDSON, of New York,
Chief Inspector of Cutaneous Diseases in Health Department and President of the Board of Pharmacy.

"I have frequently made use of **BUFFALO LITHIA WATER,** Spring No. 2, in my practice, *with excellent results.* It is a potent remedy in correcting **RHEUMATIC DIATHESIS.** In a case of **URIC ACID GRAVEL,** in which I recently prescribed it, **ITS BENEFICIAL EFFECTS WERE APPARENT AFTER THE THIRD DOSE.** I have also prescribed it with great benefit in **BRIGHT'S DISEASE OF THE KIDNEYS.**"

Water in Cases of one dozen half-gallon Bottles, Five Dollars per Case, at the Springs.

THOMAS F. GOODE,

PROPRIETOR,

BUFFALO LITHIA SPRINGS,

VIRGINIA.

JOHN WYETH & BROTHER'S

Soluble Compressed Hypodermic Tablets.

Recent improvements in our Hypodermic Compressing Machines enable us now to manufacture these tablets entirely free from any foreign material, thus insuring immediate solution and

Freedom from all possibility of Local Irritation.

Put up in cases of 10 tubes, each tube containing 20 tablets. Also, in bottles of 100 each.

SVAPNIA

OR

PURIFIED OPIUM

FOR PHYSICIANS USE ONLY.

Contains the Anodyne and Soporific Alkaloids, Codeia, Narceia and Morphia.
Excludes the Poisonous and Convulsive Alkaloids, Thebaine, Narcotine and Papaverine.

SVAPNIA has been in steadily increasing use for over twenty years, and whenever used has given great satisfaction.

To PHYSICIANS OF REPUTE, not already acquainted with its merits, samples will be mailed on application.

SVAPNIA is made to conform to a uniform standard of Opium of Ten per cent. Morphia strength.

JOHN FARR, Manufacturing Chemist, New York.

C. N. CRITTENTON, Gen'l Agent, 115 Fulton St., N. Y.

To whom all orders for samples must be addressed.

SVAPNIA IS FOR SALE BY DRUGGISTS GENERALLY.

McARTHUR'S SYRUP.

(SYR: HYPOPHOS: COMP: C. P. McARTHUR.)

Its use is indicated in Consumption and Tuberculosis, Diseases of the Chest, Chronic Cough, Throat Affections, General Debility, Brain Exhaustion, Impotence and Loss of Memory.

The point of primary importance in the use of the Hypophosphites is their *chemical* purity, but unfortunately they are too often adulterated.

So little seems to be generally known, even among the medical profession, with regard to the chemistry of the Hypophosphites, and the absolute necessity of CHEMICAL purity, that we call attention to this point.

One of the first effects produced by the use of our CHEMICALLY PURE Hypophosphites is a general increase of nervous energy, with a feeling of ease and comfort.

The second effect is an increase of appetite; digestion is improved, and the bowels become regular in their action, the quantity and color of the blood is increased, respiration is controlled, a better expansion of the chest is observed, cough improves, easy expectoration is produced, night perspiration diminishes, the face becomes fuller, the lips red, the nails and hair grow, and in children the teeth, showing the importance of the Hypophosphites on the organ of nutrition.

☞ Physicians when prescribing will please write thus:

℞ SYR: HYPOPHOS: COMP: McARTHUR. ONE BOTTLE.

As it is made *only for physicians* there are no printed wrappers or advertisements about the bottle.

Our pamphlet on the **CURABILITY AND TREATMENT OF CONSUMPTION**, sent free to physicians upon application.

We will send one bottle of McArthur's Syrup to any physician, without charge, who will pay the express charges on the same.

Mention this Journal. McARTHUR HYPOPHOSPHITE CO., BOSTON, MASS.

BUFFALO LITHIA WATER

IN THE TREATMENT OF CHRONIC GASTRIC CATARRH

CLINICAL REPORTS.

CHRONIC GASTRIC CATARRH AND URIC ACID CALCULI.

A case tated by Dr. JNO. C. COLEMAN, of Scottsburg, Va., a retired Surgeon of the U. S. Navy.

"Mr. C. was for a number of years a sufferer from **CHRONIC GASTRIC CATARRH.** While his diet *was exclusively* **TEA** and **CRACKERS, BREAD** and **MILK,** *and other similar articles,* it was frequently thrown off in an undigested state soon after taking it, and at times he discharged from an empty stomach a strongly acid glairy mucus. A marked **URIC ACID DIATHESIS** supervened, consequent upon which he suffered for a period of some two years great **VESICAL IRRITATION** and possible **CYSTITIS,** attended by pain so intense and constantly present, as to require that he should be kept for the most part under the influence of opiates. After a persistent, but ineffectual exhibition of all remedies supposed to be indicated in the case, he was put for the latter affection upon the **BUFFALO LITHIA WATER,** Spring No. 2, with the happiest possible effect.

"In a few weeks, after commencing the use of it, the irritable condition of the *Bladder* was so far relieved that he was enabled to dispense entirely with the use of opiates. At the expiration of some eight weeks he had an attack of unusual severity, from which he was relieved by the discharge of a **CALCULUS,** followed at short intervals by the discharge of three others, which proved to be the termination of this trouble, as from that time there was entire subsidence of the painful symptoms described, and the *Bladder* resumed its natural state.

"While prescribed with special reference to the relief of the *Irritable Bladder,* the action of the water was not less surprisingly happy in the **GASTRIC AFFECTION,** with remarkable promptness correcting the highly acid condition of the **STOMACH,** restoring a healthy digestion and assimilation, and *tone* and *vigor* to the depressed *Nervous System.*

"In a few months he was able to eat, with perfect impunity, the coarsest articles of diet. He is now, after a lapse of several years, in robust health, having had no return of these painful maladies."

CHRONIC GASTRIC CATARRH.

Case of JOHN P. KEELING, Esq., stated by Dr. S. S. KEELING, Norfolk, Va., Member Medical Society of Virginia.

"Mr. John P. Keeling labored under **CHRONIC DYSPEPSIA,** and was always subject to attacks of *Spasmodic Gastralgia* immediately upon taking food into the stomach, which attacks were not at all amenable to treatment. Not unfrequently the stomach *rejected everything in the way of food and drink,* and he was of necessity confined to the lightest possible articles of diet, *meat and vegetables being entirely excluded.* He became so prostrated that it was with difficulty he could walk across his chamber floor, and had often to be lifted about. Such was the state of his **NERVOUS SYSTEM** *that great solicitude was felt as to his mental condition.*

"He visited Baltimore for medical aid, and was for many months under the treatment of some of the most eminent men of the profession in that city, but without beneficial result, and was finally advised that he had nothing to hope from remedies.

"Returning in an extremely critical condition to his home in the county of Princess Anne, he came under my professional care. Satisfied that medicine was unavailing in the case, I advised the **BUFFALO LITHIA WATER,** Spring No. 2. His stomach, however, was in a highly irritable condition, and I found it necessary to administer it in very small quantities; and it was at first given not exceeding an ounce at a dose, repeated at stated intervals. At the expiration of the third day the irritability of the stomach was decidedly less, and the quantity was then increased from day to day until the thirteenth day, when I found that the patient could take twelve ounces, which I regard as maximum dose at any time. Persisting in its use, on the twenty-eighth day he was free from pain, the stomach in a normal condition readily receiving both solids and liquids in moderate quantities, strength greatly increased, and nervous symptoms entirely relieved. At the expiration of the seventh week he was able to attend actively and regularly to his business on the farm. His recovery, which I regard as one of the most remarkable I ever knew of, I attribute entirely to the **BUFFALO LITHIA WATER."**

GASTRO-INTESTINAL CATARRH.

Case of Mrs. Dr. F. J. GREGORY, of Virginia, reported by F. J. GREGORY, M.D., Keysville, Va.

"For eighteen months my wife, aged forty-one years, was a sufferer from a **GASTRO-INTESTINAL CATARRH,** which resisted my best-directed efforts at relief. The taking of the smallest quantity of the most easily-digested food on the stomach would produce an attack of *nausea and vomiting, the severity of which is seldom witnessed,* and when the stomach was free of food she would have attacks of *Gastralgia of the most excruciating nature.* She also suffered from habitual constipation, and at times with hemorrhages from the bowels. I pursued the usual line of treatment, such as simple bitters, Dilute Hydrocyanic Acid, Bismuth, etc., and called to my help two of the most skilled physicians in Southside Virginia, who supplemented my treatment with some of the newer drugs, such as **EFFERVESCING BICARB. POTASS. LACTOPEPTINE, CARLSBAD MINERAL SALTS,** etc., but with no benefit, and so her condition went on from bad to worse *until death seemed almost imminent from inanition.* I then put her on a milk diet with a glass of **BUFFALO LITHIA WATER,** Spring No. 2, every hour or so during the day, and *after the use of the first bottle improvement was marked, and before a case of it was used I regarded her cure as complete.* It has been nearly two years since, and there has been only one slight recurrence, which was a few days since, and it readily disappeared on the use of the water for a few days."

Water in cases of one dozen half-gallon bottles, $5 per case, at the Springs.

THOMAS F. GOODE, Proprietor,

BUFFALO LITHIA SPRINGS, VIRGINIA.

Sulfonal-Bayer has been before the Medical Profession for some time, receiving its unqualified endorsement, but the use has been limited in many cases, owing to the hesitation of the practitioner in recommending so costly a remedy.

It is a matter of gratification to us to be able to announce a substantial reduction in price of

THE NEW HYPNOTIC

SULFONAL-BAYER,

which will enable physicians to freely prescribe it whenever indicated, and will bring it within the reach of all classes of patients.

So much has been written and published regarding Sulfonal that it does not here seem necessary to set forth at length its peculiar merits. We have already published two pamphlets on this subject, and the points will be found to be fully exhibited in the series of contributions contained in them. These pamphlets will be mailed to applicants.

Sulfonal was discovered by Prof. Eugen A. Baumann, of Freiburg University, and was first prepared by the Farbenfabriken vorm. Friedr. Bayer & Co., Elberfeld.

Sulfonal-Bayer is supplied by us in half-ounce and one-ounce vials.

We prepare 5-grain and 15-grain Tablets of Sulfonal-Bayer. The tablet form is admirably adapted to the purpose of administering this drug, as when they are placed in the liquids they disintegrate, and are thus received into the system.

We also put up Sulfonal-Bayer in the form of our Soluble Pills, containing 5 grains each.

ANALGESIC—ANTIPYRETIC

PHENACETINE-BAYER.

Phenacetine-Bayer (Para-Acetphenetidine) is a white, glossy, crystalline powder, perfectly tasteless, slightly soluble in water, a little more soluble in glycerine, but most freely in alcohol, and it was first prepared by the Farbenfabriken vorm. Friedr. Bayer & Co., Elberfeld.

Phenacetine-Bayer has been received with great favor by the Medical Profession, and is daily growing in esteem both as an Antipyretic and Analgesic.

Phenacetine-Bayer is an important antineuralgic; its effect is more energetic than that of Antipyrine, and does not cause lassitude or any other disagreeable symptoms.

Our two pamphlets on Phenacetine-Bayer, containing the valuable testimony of eminent physicians, will be mailed on application.

W. H. Schieffelin & Co.,

170 & 172 William St., New York.

SUCCUS ALTERANS

(McDADE.)

SUCCUS ALTERANS is a purely vegetable compound of the preserved juices of Stillingia Sylvatica Lappa Minor, Phytolacca Decandra, Smilax Sarsaparilla, and Xanthoxylum Carolinianum, as collected by Dr. Geo. W. McDade, exclusively for Eli Lilly & Co., and endorsed by Dr. J. Marion Sims.

SUCCUS ALTERANS continues to gain favor from its remarkable Alterative and Tonic properties, *eliminating specific poison from the blood* and *increasing the proportion of red corpuscles in anæmic patients* to a wonderful degree; is endorsed by the medical profession, and in use by many hospitals of note.

SUCCUS ALTERANS in venereal and cutaneous diseases is fast supplanting Mercury, the Iodides, and Arsenic; and is a certain remedy for Mercurialization, Iodism, and the dreadful effects often following the use of Arsenic in skin diseases.

SUCCUS ALTERANS is also strongly recommended for its Tonic and Alterative effects in myriad forms of scrofulous disease, and in all cases where anæmia is a factor. Such patients rapidly develop a good appetite, sleep soundly, and gain flesh rapidly. Many cases are on record where patients increased ten to twenty-five pounds in weight in a few weeks.

SUCCUS ALTERANS is giving satisfactory results in treatment of *Chronic Rheumatism*, and can be used with confidence.

SUCCUS ALTERANS may be given for any length of time, without injury to the patient.

SUCCUS ALTERANS is put up in pint round amber bottles, and *never in bulk.*

PHYSICIANS who have not received Dr. McDade's latest publication, the Monographia Syphilitica, should send their address, mentioning this journal, and we will mail a copy. It contains a paper, illustrated with colored plates, by Dr. D. H. Goodwillie, of New York, on the "Sequelæ of Syphilis," reports of cases in practice, and many other valuable papers.

ELIXIR PURGANS.

Elixir Purgans (Lilly) reliably stimulates the dormant liver without undue irritation, and has gentle yet positive effect upon the alimentary tract. In Habitual Constipation, so common in Women and Children, it will be found particularly useful. Its endorsement at Bellevue and many other prominent hospitals East and West, as well as its employment in general practice by the most eminent medical men, confirms the experience of years in its use.

Each Teaspoonful Represents	
Rhamnus Purshiana, -	10 grs.
Euonymus Atropur., - -	8 grs.
Cassia Acutifolia (Purif.)	10 grs.
Iris Versicolor, - - -	4 grs.
Hyoscyamus Niger, -	2 grs.
Aromatics, etc.	

IN PRESCRIBING, PLEASE BE CAREFUL TO WRITE

ELIXIR PURGANS (LILLY),

THAT OTHER PREPARATIONS MAY NOT BE SUBSTITUTED.

HIGHLY RECOMMENDED.

We take pleasure in endorsing the Elixir Purgans (Lilly) as prepared from the above formula for in it we find a near approach to positive *perfection* in the form of a *Liquid Cathartic*, and, from our experience with the preparation, can highly recommend it to the profession.

RABUTEAU'S DRAGEES OF IRON

Laureate of the Institute of France.—Prize in Therapeutics.

The studies made by the Physicians of the Hospitals have demonstrated that the **Genuine Dragees of Iron of Rabuteau** are superior to all other preparations of Iron in cases of *Chlorosis, Anæmia, Leucorrhœa, Debility, Exhaustion, Convalescence, Weakness of Children*, and the maladies caused by the Impoverishment and Alteration of the blood after periods of fatigue, watching, and excesses of any kind.

TAKE 4 TO 6 DRAGEES DAILY.

Rabuteau's Elixir of Iron is recommended to those persons who may be unable to swallow the Dragees. Dose —*A small wineglassful with meals.*

Rabuteau's Syrup of Iron is specially designed for children. Chalybeate medication, by means of **Rabuteau's Iron,** is the most economical and the most rational known to therapeutics.

No constipation, no diarrhœa, complete assimilation.

Take only the GENUINE IRON OF RABUTEAU of

CLIN & CO., Paris.

SOLUTION OF THE SALICYLATE OF SODA OF DOCTOR CLIN.

Laureate of the Paris Faculty of Medicine (MONTYON PRIZE).

Dr. Clin's Solution, always identical in its composition, and of an agreeable taste, permits the easy administration of *pure Salicylate of Soda*, and the variation of the dose in accordance with the indications presented.

"The *Salicylate of Soda* used by **Clin** is of perfect purity, "and is prepared with the greatest care; it is a medicament "in which we may have every confidence."

—*Paris Society of Medicine, Meeting of Feb. 8th, 1879.*

Clin's Solution, very exactly mixed, contains: 2 grammes of *Salicylate of Soda* per tablespoonful, 50 centigrammes of *Salicylate of Soda* per teaspoonful.

Paris—CLIN & CO.—Paris

AND BY ALL DRUGGISTS.

CAPSULES MATHEY-CAYLUS

WITH THIN ENVELOPE OF GLUTEN.

CONTAINING COPAIBA AND ESSENCE OF SANTAL; COPAIBA, CUBEBS, AND THE ESSENCE OF SANTAL; COPAIBA, IRON, AND THE ESSENCE OF SANTAL.

"**The Mathey-Caylus Capsules,** of the *Essence of* "*Santal*, associated with the Balsams, possess an incontesta- "ble efficaciousness, and are employed with the greatest "success for the rapid cure of old or recent *Discharges,* "*Gonorrhœa, Blenorrhœa, Leucorrhœa, Cystitis of the Neck,* "*Urethritis, Catarrh*, and other *diseases of the bladder*, together "with all affections of the *Urinary Passages.*"

"Thanks to their thin envelope of *Gluten*, which is essen- "tially assimilable, the *Mathey-Caylus Capsules* are digested "by the most delicate persons, and never weary the stomach."

NEURALGIAS

PILLS OF DR. MOUSSETTE.

The **Moussette Pills** of aconitine and quinium, calm or cure *Gastralgia, Hemicrania, Headache, Sciatica,* and the most obstinate Neuralgias.

"The sedative action exerted by the **Moussette Pills** "upon the apparatus of the sanguineous circulation by the "intermediation of the vaso-motor nerves, indicates their "use in *neuralgias of the trigemini nerves,* (fifth pair), *con-* "*gestive neuralgias,* and *painful and inflammatory Rheumatismal* "*affections.*"

"Aconitine produces marvelous effects in the treatment "of *fucial neuralgias* when they are not symptomatic of "intracranial tumor."—*Society of Biology of Paris, Meeting* "*of the 28th February, 1880.*

DOSE—Take 3 to 6 pills during the twenty-four hours.

ACCEPT ONLY THE GENUINE MOUSSETTE PILLS OF

CLIN & CO.,—Paris.

GRAND NATIONAL PRIZE OF 16,600 FRANCS,

QUINA-LAROCHE

This meritorious **Elixir, QUINA-LAROCHE,** is prepared from the **three** Cinchonas; it is an agreeable and doubtless highly efficacious remedy.

—*The Lancet.*

VINOUS ELIXIR,

A STIMULATING RESTORATIVE

—AND—

ANTI-FEBRILE TONIC.

QUINA-LAROCHE under the form of a vinous **Elixir** contains the totality of the numerous principles of the **three** Cinchona barks. It is a preparation which renders great services to Therapeutics.—Extract of the *Gazette des Hôpitaux*, Paris.

FAR SUPERIOR TO ALL ORDINARY CINCHONA WINES.

LAROCHE'S QUINA, tried by the Academy of Medicine of Paris, is a specially prepared COMPOUND EXTRACT of Quinquina, a careful analysis, confirmed by experience, has shown that most of the wines and syrups hitherto used have not contained all the properties of this precious bark, of these some, although beneficial, are altogether lost, while many preparations contain but half the properties of the bark in varying proportions.

MR. LAROCHE, by his peculiar method, has succeeded in extracting all the active principles of the quinquina, combining these with *Catalan Wine* forming an Elixir free from the disagreeable bitterness of other similar preparations. Practitioners have found triple advantages in the use of this Elixir, it is a *strong tonic,* is easily administered, and perfectly harmless, being free from the unpleasant effects of Quinine.

THE FERRUGINOUS QUINA-LAROCHE is the invigorating tonic *par excellence,* having the advantage of being easily assimilated by the gastric juice; without, in any way, deranging the action of the digestive organs, proving itself to be a most efficacious remedy in cases of impoverishment of the blood, ANÆMIA, CHLOROSIS, INTESTINAL HÆMORRHAGE, CASTRALGIA, EXHAUSTION, ETC., ETC.

BROMIDIA

THE HYPNOTIC.

FORMULA.—

Every fluid drachm contains 15 grains EACH of Pure Chloral Hydrat. and purified Brom. Pot., and one-eighth grain EACH of gen. imp. ext. Cannabis Ind. and Hyoscyam.

DOSE.—

One-half to one fluid drachm in WATER or SYRUP every hour, until sleep is produced.

INDICATIONS.—

Sleeplessness, Nervousness, Neuralgia, Headache, Convulsions, Colic, Mania, Epilepsy, Irritability, etc. In the restlessness and delirium of fevers it is absolutely invaluable.

IT DOES NOT LOCK UP THE SECRETIONS.

PAPINE

THE ANODYNE.

Papine is the Anodyne or pain-relieving principle of Opium, the Narcotic and Convulsive Elements being eliminated. It has less tendency to cause Nausea, Vomiting, Constipation, Etc.

INDICATIONS.—

Same as Opium or Morphia.

DOSE.—

(ONE FLUID DRACHM)—represents the Anodyne principle of one-eighth grain of Morphia.

IODIA

The Alterative and Uterine Tonic.

FORMULA.—

Iodia is a combination of active principles obtained from the Green Roots of Stillingia, Helonias, Saxifraga, Menispermum, and Aromatics. Each fluid drachm also contains five grains Iod. Potas., and three grains Phos. Iron.

DOSE.—

One or two fluid drachms (more or less as indicated) three times a day before meals.

INDICATIONS.—

Syphilitic, Scrofulous and Cutaneous Diseases, Dysmenorrhea, Menorrhagia, Leucorrhea, Amenorrhea, Impaired Vitality, Habitual Abortions, and General Uterine Debility.

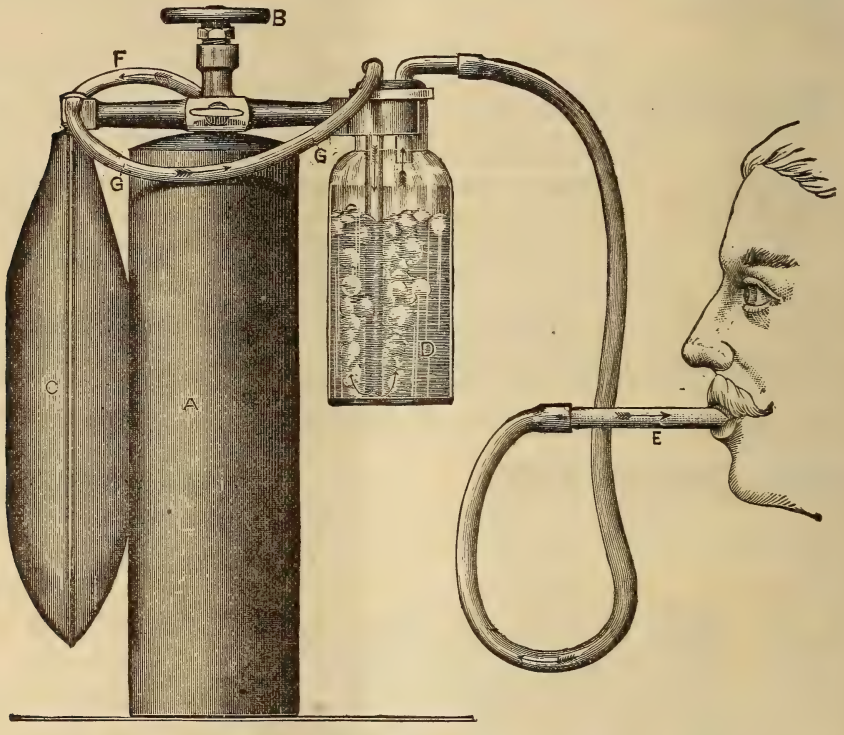
INHALATION APPARATUS

FOR

THE THERAPEUTIC ADMINISTRATION OF OXYGEN.



In the treatment of lung troubles by Oxygen its exhibition by inhalation is preferred. The apparatus herewith shown is a modification of the Nitrous Oxide apparatus which we have supplied for many years. It is made in the best manner throughout, and is the outcome of years of experience in the manufacture of gas apparatus. It will be found to meet all the requirements.

We supply the gas in two sizes of cylinders, containing respectively forty and one hundred gallons, either pure Oxygen, or a mixture of Oxygen and Nitrous Oxide in definite proportions of 20 per cent., and forty per cent. of Nitrous Oxide.

Whether pure or mixed the gas is sold at the uniform price of 5 cents a gallon. The cost of the cylinders will be refunded on their return empty with the valves in good condition. Full description of Inhalation and Enema apparatuses with directions for use accompany each apparatus, or will be supplied on application.

PRICES.

Inhalation Apparatus	$5.00
Cylinder, 40 gallons' capacity	6.00
40 gallons Gas, either pure Oxygen or mixed Oxygen and Nitrous Oxide	2.00
Complete Apparatus, Cylinder, and 40 gallons Gas	$13.00
Inhalation Apparatus	$5.00
Cylinder, 100 gallons' capacity	15.00
100 gallons Gas, either pure or mixed	5.00
Complete Apparatus, Cylinder, and 100 gallons Gas	$25.00

THE BEST ANTISEPTIC
FOR BOTH INTERNAL AND EXTERNAL USE.

ANTISEPTIC, PROPHYLACTIC, DEODORANT.

LISTERINE

NON-TOXIC, NON-IRRITANT, NON-ESCHAROTIC.

FORMULA—Listerine is the essential antiseptic constituent of Thyme, Eucalyptus, Baptisia, Gaultheria and Mentha Arvensis, in combination. Each fluid drachm also contains two grains of refined and purified Benzo-boracic Acid.

DOSE—Internally: One teaspoonful three or more times a day (as indicated) either full strength, or diluted, as necessary for varied conditions.

LISTERINE is a well-proven antiseptic agent—an antizymotic—especially adapted to internal use, and to make and maintain surgical cleanliness—asepsis—in the treatment of all parts of the human body, whether by spray, irrigation, atomization, or simple local application, and therefore characterized by its particular adaptability to the field of

PREVENTIVE MEDICINE—INDIVIDUAL PROPHYLAXIS.

Diseases of the Uric Acid Diathesis.

LAMBERT'S

LITHIATED HYDRANGEA

KIDNEY ALTERATIVE—ANTI-LITHIC.

FORMULA—Each fluid drachm of "Lithiated Hydrangea" represents thirty grains of FRESH HYDRANGEA and three grains of CHEMICALLY PURE Benzo-Salicylate of Lithia. Prepared by our improved process of osmosis, it is INVARIABLY of DEFINITE and UNIFORM therapeutic strength, and hence can be depended upon in clinical practice.

DOSE—One or two teaspoonfuls four times a day (preferably between meals).

Urinary Calculus, Gout, Rheumatism, Bright's Disease, Diabetes, Cystitis, Hæmaturia Albuminuria, and Vesical irritations generally.

We have much valuable literature upon { GENERAL ANTISEPTIC TREATMENT, LITHEMIA, DIABETES, CYSTITIS, ETC. } To forward to Physicians upon request.

LAMBERT PHARMACAL CO., ST. LOUIS, MO.

California Vintage Co.

21 Park Place N.Y.

Geo Hamlin Prest. Chas Roome Parmele Treas.

GENTLEMEN:

The Case of your wines sent me for analysis by Dr. A. L. Hummel, of the "Annals of Hygiene," containing specimens of your La Rosa Zinfandel, Mataro, Riesling, Royal Tokay, and Royal Grape Brandy, has been duly received.

I have examined them for the common contaminants of wine; to wit: Sulphurous acid and sulphites, salicylic acid, fuchsin, lead salts, etc., none of which I found present therein.

I have also determined their alcoholic strength, extractives, and ashes, and found them to correspond strictly in this respect with the standard of pure and natural wines, which cannot be said of many of the imported wines.

As a native of a wine-producing country, I consider myself somewhat of a judge of wines, and regard your products as comparing more than favorably with most of the wines from abroad which are sold at higher prices, so much so that I enclose within my order for fifty bottles of La Rosa Zinfandel, which I expect to use hereafter exclusively at my table.

Very Respectfully,

L. WOLFF, M.D.,
Demonstrator of Chemistry, Jefferson Medical College.

McARTHUR'S SYRUP.

(SYR: HYPOPHOS: COMP: C. P. McARTHUR.)

Its use is indicated in Consumption and Tuberculosis, Diseases of the Chest, Chronic Cough, Throat Affections, General Debility, Brain Exhaustion, Impotence and Loss of Memory.

The point of primary importance in the use of the Hypophosphites is their *chemical* purity, but unfortunately they are too often adulterated.

So little seems to be generally known, even among the medical profession, with regard to the chemistry of the Hypophosphites, and the absolute necessity of CHEMICAL purity, that we call attention to this point.

One of the first effects produced by the use of our CHEMICALLY PURE Hypophosphites is a general increase of nervous energy, with a feeling of ease and comfort.

The second effect is an increase of appetite; digestion is improved, and the bowels become regular in their action, the quantity and color of the blood is increased, respiration is controlled, a better expansion of the chest is observed, cough improves, easy expectoration is produced, night perspiration diminishes, the face becomes fuller, the lips red, the nails and hair grow, and in children the teeth, showing the importance of the Hypophosphites on the organ of nutrition.

☞ Physicians when prescribing will please write thus:

℞ SYR: HYPOPHOS: COMP: MCARTHUR. ONE BOTTLE.

As it is made *only for physicians* there are no printed wrappers or advertisements about the bottle.

Our pamphlet on the **CURABILITY AND TREATMENT OF CONSUMPTION,** sent free to physicians upon application.

We will send one bottle of McArthur's Syrup to any physician, without charge, who will pay the express charges on the same.

Mention this Journal. McARTHUR HYPOPHOSPHITE CO., BOSTON, MASS.

Intestinal Diseases of Children.

"In Cholera Infantum," says Dr. Louis Starr, "the irritability of the stomach is a formidable barrier to alimentation; nevertheless, every effort must be made to give food in small quantities and at short intervals." Clinical experience, the only conclusive test, has proved the great efficacy in this disease, of MELLIN'S FOOD dissolved in water only and given cold, in small amount frequently repeated. "In MELLIN'S FOOD," says Dr. Eustace Smith, "the whole of the starch is converted into dextrine and grape sugar (properly maltose) so that the greater part of the work of digestion is performed before the food reaches the child's stomach." He also says, "I have never seen any signs of fermentation which I could attribute to the influence of maltose." As it is non-fermentable and so quickly assimilated, MELLIN'S FOOD is the best food for infants suffering from this complaint until convalescence has been sufficiently established to allow the regular diet to be resumed.

A sample of MELLIN'S FOOD will be sent to any physician, free of all expense, upon application

THE VALUE OF NUTRITION IN DISEASE.

All physicians who have ever used Murdock's Liquid Food and Suppositories recognize their value over all other foods, in breaking up disease and building up the patients after disease, preventing a relapse, **as the same results are obtained as in surgery.** Its value in surgical cases we illustrate by the records of the different cities and of Murdock's Free Surgical Hospital for Women, which is the largest in the United States. It contains 114 beds, every bed free, including operation, the operations ranging from 1000 to 1200 yearly, representing 90 of the worst classes known in surgery. Among these cases we have had **Cancer of uterus** (*Kolpo-hysterectomy*), 13; **Salpingitis** (*Tait's operation*), 31; **Fibroid of uterus** (*abdominal hysterectomy*), 19; **Ventral operation, hernia,** (*abdominal section*), 12; **Cancer of bowel** (*incision*), 2; **Parovarian cyst, 6; Papillomatous cyst** (*extirpation*), 4; **Tubercular peritonitis** (*incision*), 1, **Ovarian cystoma 27; Nymphomania** (*Battey*), 1; **Exploratory abdominal incisions, 12; Fibroid with abdominal abscess** (*Hegar*), 2; **Hysterorraphy, 2; Dermoid cyst, 3; Cirrhotic ovaries,** (*Battey*), 4; **Fibroid uterus** (*Hegar*), 6; **Hystero-epilepsy** (*Battey*), 1; **Haemato-Salpinx** (*Tait*), 5; **Rupture of intestine into vagina, 1; Dislocated kidney, 2; Fibroid tumor abdominal wall, 1; Resection of intestine** (*Senn*), 1; **Ruptured perineum, 294.** Patients are in the Hospital 8 days before and 26 days after operation, on an average.

In Boston, last year, 42 deaths were from Cancer in the Breast. In Murdock's Hospital, 35 such cases were operated on without a death, the patients remaining in the Hospital, on an average, 18 days.

Mortality	in Boston,	25.60	per 1000.
"	of Women in Boston,	29,00	" "
"	in **Murdock's Free Surgical Hospital,**	**5.00**	" "
"	New York,	26.32	" "
"	Philadelphia,	20.00	" "
"	Chicago,	20.90	" "
"	St. Louis,	20.49	" "

showing our mortality is only one-sixth as great as of those in health. As good results were obtained in our General Hospital, which we kept open 27 months, **thus showing the value of nutrition as found in Murdock's Liquid Food, and so recognized by the British and American Medical Associations,** before which essays were read and discussed, and it is the only Raw food preparation on which essays were ever read.

Physicians are invited to visit our Hospitals and Works, also to send in patients and to be present at the operations. For any physician who has not used our Liquid Food (and Suppositories for adults and infants), we will deliver free samples to any express company in Boston.

When babies do not thrive, never change their food, but add five or more drops at each feeding of Murdock's Liquid Food, and their lost or needed vitality will be restored in less than thirty days. It is invaluable when weaning babies or when teething. If mothers will take one teaspoonful to a tablespoonful before each meal and on retiring, they will receive as much benefit as the baby.

Murdock Liquid Food Co., Boston.

CELERINA

NERVE TONIC, STIMULANT AND ANTISPASMODIC.

FORMULA.—Every Fluid Drachm represents FIVE grains EACH—Celery, Coca, Kola, Viburnum and Aromatics.

INDICATIONS.—Loss of Nerve-Power (so usual with Lawyers, Preachers, Writers and Business Men), Impotency, Spermatorrhea, Nervous Headache, Neuralgia, Paralysis, Hysteria, Opium Habit, Inebriety, Dyspepsia, and ALL LANGUID conditions of the System.

Indispensable to restore a patient after alcoholic excess.

DOSE.—One or two Teaspoonfuls three or more times a day, as directed by the Physician.

LIQUID IRON-RIO

Palatable and easily assimilated. Does not produce Nausea, nor irritate the Stomach. Does not Cause Headache, nor Constipate. Does not Stain the Teeth. It is so Acceptable to the Stomach that its Use is Admissible when all other forms of Iron would be rejected. Being so Readily Assimilable, it only requires a small Dose.

Each Fluid Drachm contains ONE GRAIN of Iron in a Pleasant and Digestible Form.

DOSE.—One or more Teaspoonfuls as indicated, during or after meals.

S. H. KENNEDY'S

CONCENTRATED EXTRACT OF

PINUS CANADENSIS

PHILADELPHIA.

SPORTING AND ATHLETIC GOODS OF EVERY DESCRIPTION.

No Chemicals.

W. BAKER & CO.'S
Breakfast
Cocoa
Is Absolutely Pure,
and it is Soluble.

To increase the solubility of the powdered cocoa, various expedients are employed, most of them being based upon the action of some alkali, potash, soda or even ammonia. Cocoa which has been prepared by one of these chemical processes, can usually be recognized at once by the distinct alkaline reaction of the infusion in water.

W. Baker & Co.'s Breakfast Cocoa is manufactured from the first stage to the last by perfect mechanical processes, **no chemical being used in its preparation.** By one of the most ingenious of these mechanical processes the greatest degree of fineness is secured without the sacrifice of the attractive and beautiful red color which is characteristic of an absolutely pure and natural cocoa.

BOUDAULT'S PEPSINE

The only Pepsine used in the Hospitals of Paris for the last Thirty Years.

Unlike the various substitutes which, in most cases, are but unscientific or incompatible compounds, forced upon the Medical Profession as aids to digestion by extensive advertising, but which, when submitted to the proper tests, are found to be useless as digestive agents, Pepsine is constantly gaining in the esteem of the careful practitioner.

Since the introduction of Pepsine by Boudault and Corvisart in 1854, the original BOUDAULT'S PEPSINE HAS BEEN AT ALL TIMES CONSIDERED THE BEST, as is attested by the awards it has received at the Expositions of 1867, 1868, 187 1873, in 1876 at the Centennial Exposition of Philadelphia, and in 1878 at the Paris Exposition.
